Ook-Ho6747-201-RP331

NATURE

A WEEKLY JOURNAL OF SCIENCE

"To the solid ground
Of nature trusts the Mind that builds for aye"—WORDSWORTH

201

N. Cl. 5/8/63

Volume 197

JANUARY 5, 1963, to MARCH 30, 1963

LONDON
MACMILLAN AND CO., LTD.
NEW YORK: ST. MARTIN'S PRESS, INC.

INDEX

AANENSEN, C. J. M., and J. S. Sawyer: The Gale of February 16, 1962, in the West Riding of Yorkshire, 654
Aarkrog, A.: Cæsium-137 from Fall-out in Human Milk, 667
Abbreviated Pelagic Life of Chilean and New Zealand Oysters (R. H. Millar and P. J. Hollis), 512
Abderhalden, Rudolph: Clinical Enzymology: Enzymes in Pathogenesis. Diagnosis and Therapy, *review* by Dr. H. Lehmann, 735
Abdullah, M., and W. J. Whelan: Enzymatic Debranching of Glycogen, 979
Abelson, D., and A. Boyle: Photochemistry of a Nicotinamide Metabolite, N′-Methyl-4-Pyridone-3-Carboxamide, 460
Abood, L. G., *et al.*: A Possible Mechanism of Action of Calcium and some Psychotomimetic Agents on Membranes, 367
Abrupt Phase Shifts on *MSF* (60 kc/s) (A. M. J. Mitchell, R. L. Corke and J. McA. Steele), 580
Absolute Energy Distribution in the Optical Spectrum of 3C 273 (Dr. J. B. Oke), 1040
Absorption Spectra in Irradiated Water and Some Solutions (J. W. Boag and E. J. Hart), 45; (J. P. Keene), 47
Abyssal Crustacea (J. Laurens Barnard, Robert J. Menzies and Mihai C. Băcescu), *review* by Dr. Isabella Gordon, 217
Academy of Sciences, U.S.S.R.: Kirillin, V. A.: elected a vice-president, 649
  Paton, B. E.: elected a member of the Presidium, 649
Accelerators: Particle (Prof. M. Stanley Livingston and Dr. John P. Blewett), *review* by W. Walkinshaw, 1236
Accumulation of Free Proline during Yeast Sporogenesis (C. Ramirez and J. J. Miller), 722
Accumulation of Hæmatins by Polychætes (R. P. Dales), 1302
Accumulation of Radium-226 by the Freshwater Gastropod *Lymnaea stagnalis* L. (O. Van der Borght), 612
Accumulation of Ribonucleic Acid in *Escherichia coli* due to the Action of 5-Methyl Tryptophan (G. Turnock and D. G. Wild), 597
Acetaldehyde on the Resorcinol Test for Fructose: Effect of (G. P. Arsenault and W. Yaphe), 181
ε-Acetamide Caproic Acid: Protection of the Skin Homografts by (A. Bertelli and G. Frontino), 510
Acetate Ions: Complex Formation between Lead(II) Ions and (Sylvia Gobom), 283
Acetone: Some Products of the γ-Radiolysis of Liquid (J. Kučera), 279
Acetylcholine-like Activity released from Brain *in vivo*: Nature of (J. C. Szerb), 1016
Acetyl Derivatives of Muramic Acid (P. M. Carroll), 694
Acetyl Radical: Electron Paramagnetic Resonance Spectrum of the (J. R. Morton and W. E. Falconer), 1103
Acid Leaching of Uranium and Thorium Carbides (P. L. Pauson, M. McLean and W. J. Clelland), 1200
Acid Phosphatase and Cathepitc Activity in Rheumatoid Synovial Tissue (M. Luscombe), 1010
Acid–Schiff-positive Component of the Medullary Bone of the Laying Domestic Fowl: Periodic (D. Conkie), 808
Acid Solution: Apparent Molecular Weight of Insulin in Dilute (P. D. Jeffrey and J. H. Coates), 1104
Ackerman, G. A.: Histochemical Demonstration of Aminopeptidase Activity in the Cells of the Blood and Bone Marrow from Various Hæmatological Disorders, 189
Acorn Lecture, "Bird Protection in Scotland", 652
Acoustic Confusions and Memory Span for Words (R. Conrad), 1029
Acoustic Technology: Society of (formation), 23
Actinomycin *D* and Puromycin: Inhibition of the Biological Action of Thyroid Hormones by (Dr. J. R. Tata), 1167
Activation Analysis of Paper Chromatograms for Iodine ($^{127}I \longrightarrow ^{128}I$), (A. Dimitriadou, P. C. R. Turner and Prof. T. Russell Fraser), 446
Activation Analysis of Particulate Air Contaminants (T. F. Parkinson and L. G. Grant), 479
Activation Product and the Fibrinolytic System (Christine Hawkey), 162
Activity of Fusimotor Fibres innervating Muscle Spindles in the Intercostal Muscles of the Cat (T. A. Sears), 1013
Activity of Gibberellin 'D' on the Germination of Photosensitive Lettuce Seeds (H. Ikuma and K. V. Thimann), 1313
Actomyosin-like Protein in Mitochondria of the Mouse Liver (S. A. Neifakh and T. B. Kazakova), 1106
Adair, J., *et al.*: A Secondary Induced Thiamine Deficiency in Mink, 810
Adams, B. G., *et al.*: Estimation of Methylpentynol, 83
Adams, D. H., and B. M. Bowman: An Anti-Virus Action of Azaserine-Thioguanine *in vivo*, 316
Adams, Dr. J. B.: Elected a Fellow of the Royal Society, 1251
Adams, J. B.: Presence of Œstrogen Sulphokinase in Chick Embryonic Cartilage, 1007
Adams, P. H., *et al.*: Source of the Gastric Mucosal Potential Difference, 874
Adams, R. A.: Cheek Pouch of the Syrian Hamster and Immunity to Heterotransplantation of a Murine Leukæmia, 1021
Adamski, T.: Comminution of Crystal Nucleation of a Precipitation Method, 894
Adamski, T., and L. Trojanowski: Possible Radiation Damage Effects in Barium Chromate Crystals, 1005
Adaptive Teaching Machines (196, 1276), *erratum*, 652
Adenine in Aerated and De-Aerated Aqueous Solutions: Effect of Ionizing Radiation on (Miss J. J. Conlay), 555
Adenocarcinoma (*72J*) and Spontaneous Mouse Breast Tumours: Effect of a New Anticancer Agent, 1,4-Dimethyl-1,4-Diphenyl-2-Tetrazene, on a Transplantable Mammary (A. W. Vogel, *et al.*), 85
Adenosine Diphosphate on the Concentration of Platelets in Circulating Blood: Effect of (Prof. G. V. R. Born and Dr. M. J. Cross), 974
Adenosine Triphosphatase Activity of Glycerinated Muscle Fibres in a Mechanical Field (Tsuyoshi Ohnishi and Tomoko Ohnishi), 184
Adenosine Triphosphate: Stimulation of Insulin Secretion *in vitro* by (J. L. R-Candela, *et al.*), 1304
Adenosine Triphosphate. Stimulation of Secretion of Insulin by J. L. R-Candela and M. C. Garcia-Fernandez), 1210
Adenosine Triphosphate/Adenosine Diphosphate in Platelet-rich Plasma in Hæmorrhagic Disorders. Ratio (Von Willebrand and Glanzmann Disease) (J. P. Caen), 504
Adipose Tissue Lipoprotein Lipase Activity in Rats of, Two Different Ages (C. Chlouverakis, 196, 1103), *erratum*, 341
Adipose Tissue of Obese–Hyperglycæmic Mice: Lipase and Glycerokinase Activities in the (Serene Lochaya, *et al.*), 182
Adjuvant (Freund's): Thymus–Lymphatic Nodes Interrelations Following Injection of (Dr. George J. Svet-Moldavsky and L. I. Raffkina), 52
Adkins, J. E.: Appointed Professor of Theoretical Mechanics, 132
Adman, R., *et al.*: Hydrogen and Chlorine Hyperfine Splittings of Several 2-Hydroxy-1,4-naphthosemiquinones, 74
Adolescence: Growth at (Dr. J. M. Tanner), second edition, *review* by Prof. Douglas Hubble, 115
Adrenal Incubates of Patients with Arterial Hypertension: Isolation of a Polar Aldosterone-like Substance from the Urine and (H. E. Carr, jun., and I. Nauklarinen), 696
Adrenalectomy on Histamine Metabolism in the Rat: Effect of (J. M. Telford), 600
Advances in Comparative Physiology and Biochemistry (edited by O. Lowenstein), Vol. 1, *review* by Prof. D. C. Harrison, 526
Advances in Inorganic Chemistry and Radiochemistry, Vol. 4 (edited by Prof. H. J. Emeléus and Dr. A. G. Sharpe), *review* by Dr. D. W. A. Sharp, 325
Advances in Protein Chemistry (edited by C. B. Anfinsen, jun., M. L. Anson Kenneth Bailey and John T. Edsall), Vol. 15, *review* by Dr. Brian S. Hartley, 423
Advances in Space Science and Technology. (Edited by Frederick I. Ordway III), Vol. 4, *review* by D. G. King-Hele, 420
Advances in Veterinary Science, Vol. 7 (edited by C. A. Brandly and E. L. Jungherr), *review* by Prof. H. Burrow, 1036
Advisory Council on Scientific Policy in Britain, 825
  Annual Report 1961–1962 (Cmnd. 1920), 825, 851
Aerobacter cloacae: Sulphydryl Groups Essential for the Penicillinase Activity of (J. T. Smith), 900
Aerodynamics: G. S. Ram appointed Research Fellow in, 132
Aeronautical Systems Division and the Aerospace Medical Division, United States Air Force Systems Command: Second Bionics Symposium, "Information Processing by Living Organisms and Machines", 955
Aerosol: Hypercritical (M. M. Benarie), 486
Affinity of Steroids for Electrons with Thermal Energies (J. E. Lovelock, P. G. Simmonds and W. J. A. Vandenheuvel), 249
Agar-gel Electrophoresis: Application to Belgian and Barundi Populations: Determination of Haptoglobin-groups Frequencies by Starch-gel and (M. van Sande, *et al.*), 603
Agar-gel Plate: Visualization of Different Diphospho- and Triphospho-pyridine Nucleotide Dehydrogenase Isozymes on an (G. Broun and S. Avrameas), 1208
Agaric Family Bolbitiaceae using Herbarium Material: Germination of Basidiospores and Production of Fructifications of Members of the (R. Watling), 717
Age: Evidence for a Sex Difference: Change of Human Chromosome Count Distributions with (Patricia A. Jacobs, *et al.*), 1080
Age Changes of the Thymus in Two High-leukæmia Strains of Mice, *SL* and *AKR*, and in their F_1 Hybrids (K. Nakakuki and Y. Nishizuka), 1217
Age Determination of some Yugoslav Granites and Granodiorites of the Rubidium/Strontium Method (Z. Cervenjak, G. Ferrara and E. Tongiorgi), 893
Agglutination Tests: Passive (Edgar Pick and D. Nelken), 157; (N. Gilboa-Garber and D. Nelken), 158
Aghion, J., *et al.*: Solvent-Induced Changes in the Absorbancy of Isolated Chloroplast Fragments, 1110
Agricultural Research Council: *Farm Buildings Research*, 130
  Radiobiological Laboratory. Annual Report, 1961–62, 241
Ahrens, L. H.: Neutron Numbers 98, 108 and 116, 993
Ailleret, P. M. J.: Awarded the Faraday Medal of the Institution of Electrical Engineers, 955
Air: Earth, Sea and, a Survey of the Geophysical Sciences (Prof. Jerome Spar), *review* by Prof. S. K. Runcorn, 524
Air: Topography of Kish Crystals and the Effect of Oxidation in (P. L. Walker, jun., and B. C. Banerjee), 1291
Air and Argon: Oxidation of Plutonium in Moist (J. B. Raynor and J. F. Sackman), 587
Air at Ground-level during 1960 and 1961: Seasonal Variations of Cæsium-137 in (K. G. Vohra, *et al.*), 1092
Airborne Radar (Donald J. Povejsil, Robert S. Raven and Peter Waterman), (Principles of Guided Missile Design), *review* by R. Aspinall, 220
Aircraft Propulsion: R. J. L. McLaren appointed Research Fellow in, 132
Akaboshi, M., *et al.*: Chemical Protection for the Incorporation of Phosphorus-32 into Nucleic Acids of Lymphatic Cells against γ-Irradiation, 914
Alačević, M.: Interspecific Recombination in *Streptomyces*, 1323
Albedo and Polarization Measurements: Determination of Relative Ages of Lunar Craters by (G. Fielder), 69
Albumin in Human Plasma: Separation of Polypeptides bound by (A. L. Rubin, *et al.*), 1009
Alcaligenes faecalis and the Host-range of *A. faecalis* Bacteriophages: Lysogeny in (I. J. Maré and J. N. Coetzee), 1322

INDEX

Alcohol Dehydrogenases: Interpretation of Inhibition Kinetics of Coenzyme-substrate Reactions, and the Role of Zinc in (Dr. K. Dalziel), 462
Alder, Henry L., and Edward B. Roessler: Introduction to Probability and Statistics, *review* by W. Brass, 1138
Aldolase in Lenses of Lactose-fed Rats: Glucose-6-phosphate Dehydrogenase and (I. Korc and M. Calcagno), 690
Aldrin and Isodrin by the Adult Housefly *in vivo*: Significance of the Epoxidation of the Isomeric Insecticides (G. T. Brooks, *et al.*), 311
Alexander, Dr. A. A., *et al.*: Periodic Nature of Spontaneous Peripheral Nervous System Activity, 1169
Alexander, J. B., and K. J. Muller: Devonian Conodonts in Stratigraphic Succession of Malaya, 681
Alexander, P., and R. J. Black (edited by): A Laboratory Manual of Analytical Methods of Protein Chemistry (including Polypeptides), Vol. 3, *review* by Dr. D. T. Elmore, 113
Alexander, Peter, and Z. M. Bacq: Fundamentals of Radiobiology, revised, second edition, *review* by Dr. E. V. Hulse, 931
Ali, S. Y., *et al.*: Glycoprotein Excretion following the Injection of Papain into Rabbits, 707
Alkali Metals, and to Itself: Binding of Xenon to Halogens, to (L. C. Allen), 897
Alkaline Earths in Heparin (G. E. Harrison and Alice Sutton), 809
Alkaloids in Rumen Liquor: Vitamin B_{12} and the Detoxification of Hepatotoxic Pyrrolizidine (A. T. Dick, *et al.*), 207
Alkyd Resin Technology: Formulating Techniques and Allied Calculations (T. C. Patton), *review* by A. I. Escolme, 736
Allbrook, Prof. D., and Dr. W. W. Bishop: New Fossil Hominoid Material from Uganda, 1187
Allelic Immobilization Antigens in *Paramecium aurelia*: Chemical and Immunological Comparisons of (I. G. Jones and G. H. Beale), 205
Allen, D., *et al.*: Estimation of Methylpentynol, 83
Allen, Sir George: Retires as Secretary from the British Association for the Advancement of Science, 128
Allen, L. C.: Binding of Xenon to Halogens, to Alkali Metals, and to Itself, 897
Allerhand, J., *et al.*: An Endotoxin-like Fraction extracted from the Cells of *Candida albicans*, 516
Allibone, Dr. T. E.: Appointed the Rutherford Memorial Lecturer for 1963–64, 438
Allison, Dr. A. C.: Malaria and Glucose-6-phosphate Dehydrogenase Deficiency, 609
Allison, Dr. A. C., *et al.*: Polarographic Measurements of Electron Donation and Acceptance by Carcinogenic Compounds, 764
Allison, Dr. A. C., and T. Nash: Electron Donation and Acceptance by Carcinogenic Compounds, 758
Allotypic Specificity in the Mouse (MuA2): A New (S. Dubiski and B. Cinader), 705
Alloxan Diabetic Rat: Decreased Erythrocyte Survival in (E. S. Younathan and H. N. Marvin), 85
Alonso, M., *et al.*: Loss of the Haemagglutinating Capacity of Fowl-plague Virus after Culture on HeLa Cells, 926
Alpha-Keratin: Density and Structure of (P. Mason), 179
Alteration of Steroid Dehydrogenase Synthesis in a Mutant of *Pseudomonas testosteroni* (J. D Teller and A. M Bongiovanni), 1112
Alterations in Skeletal Muscle after X-Irradiation and their Similarity to Changes in Muscular Dystrophy (R. M. Dowben and L. Zuckerman), 400
Alty, Dr. T.: Appointed deputy principal, University of Birmingham, 952
Aluminium Alloys: Electrolytic Detachment of Anodic Oxide Films on (R. C. Spooner), 995
Aluminium Nitride Whiskers (P. E. Evans and T. J. Davies), 587
Alvager, T., *et al.*: A Direct Terrestrial Test of the Second Postulate of Special Relativity, 1191
Alzheimer's Disease: Paired Helical Filaments in Electron Microscopy of (M. Kidd), 192
American Association for the Advancement of Science: Miscellaneous Publication No. 62–3: *Science and the Public Mind: A Memorandum for E. G. Sherburne, jun., from Wilbur Schramm*, 437
American Chemical Society: Substance of an address given by Prof. N. P. Badenhuizen, at the one hundred and forty-second Meeting, 464
American Institute of Biological Sciences. High School Biology. Revised edition, *review* by Dr. L. M. J. Kramer, 4
American Museum of Natural History: Annual Report, 1961/62, 1155
American Scientists and Nuclear Weapons Policy (Robert Gilpin), *review* by R. Brightman, 1035
American Society of Pharmacognosy: Election of Officers, 438
Amiel, S., *et al.* Neutron Activation Analyses of Snake Venoms: Presence of Copper, 383
Amines: Spectrophotometric Micro-Estimation of some Simple Plant (M. Richardson), 290
Amines with Chloranil: Interaction of Amino-Acids, Proteins and (Dr. J. B. Birks and Dr. M. A. Slifkin), 42
Amino-Acetonitrile of the Necrosis induced by Bromobenzene. Topographic Distribution of Hepatic Necrosis in Bromobenzene, Thioacetamide, Tannic Acid Poisoning and Inhibition by (L. Fiume), 394
Amino-Acid by Root Nodules of *Galega officinalis*: Incorporation of (Dr. M. H. Proctor and Essam Moustafa), 262
Amino-Acid Copolymer: Distribution of Radioactive Sulphur after Oral Administration to the Rat of a Water-insoluble Fraction of Sulphur-35-labelled Thermal (F. Knappen and G. Krampitz), 289
Amino-Acid Sequence: Antigenicity of Synthetic Polypeptides with known (Prof. A. E. Axelrod, *et al.*), 146
Amino-Acid Transport in Ehrlich Cells: Evidence for Two Types of Mediation of Neutral (Dale L. Oxender and Halvor N. Christensen), 765
Amino-Acids: Presence of a Phosphatido-peptide Fraction in Liver Cell Membrane and its Possible Role in the Active Transport of (E. Tria and O. Barnabei), 598
Amino-Acids: Reversal of *o*-Nitrobenzoic Acid Inhibition of Microbial Growth by (Jerry J. Kirkland and Norman N. Durham), 210
Amino-Acids by Electron Spin Resonance at Very Low Temperature: Examination of Optically Excited (P. Douzou, *et al.*), 1105
Amino-Acids during Metabolism in *Escherichia coli*: Utilization of (Yukio Kameda, *et al.*), 314
Amino-Acids on Phenylalanine–Tyrosine-supplemented Diets: Urinary (M. J. Carver and R. Paska), 493
Amino-Acids, Proteins and Amines with Chloranil: Interaction of (Dr. J. B. Birks and Dr. M. A. Slifkin), 42
Amino-Acids with Riboflavin: Interaction of (M. A. Slifkin), 275
γ-Aminobutyric Methylester on a Preparation of Toad's Sinus–Atrium: Cholinergic–Adrenergic Dual Action of (Koroku Hashimoto, *et al.*), 500
Amino Groups in Insoluble Specimens: Use of the Ninhydrin Reaction for Quantitative Estimation of (P. A. Kendall), 1305
Aminopeptidase Activity in the Cells of the Blood and Bone Marrow from Various Haematological Disorders. Histochemical Demonstration of (G. A. Ackerman), 189
Aminopeptidase of Human Tissues and Serum: Electrophoretic Behaviour of an (E. E. Smith and A. M. Rutenburg), 800
Ammonium Sulphate with the Estimation of Proteins by the Biuret Reaction: Interference by (P. G. Stanley), 1108
Amoebiasis: Effects of Corticosteroids on Experimental (S. Teodorovic, *et al.*), 86
Amoroso, E. C., *et al.*: Growth of Transplantable Cancer in Rats previously injected with Placental Tissue, 606
Amphetamine–Barbiturate Mixtures: Dose-response Relations of (R. Rushton and H. Steinberg), 1017
α-Amylase: Dextran-gel Filtration in the Purification of a Crustacean (A. H. Blandamer and R. B. Beechey), 591
Amyloid: Relationship of Gamma-Globulin to the Fibrils of Secondary Human (A. S. Cohen and W. E. Paul), 193
Amylopectin in the Starch Granule. Formation and Distribution of Amylose and (Prof. N. P. Badenhuizen), 464
Amylose and Amylopectin in the Starch Granule: Formation and Distribution of (Prof. N. P. Badenhuizen), 464
Amylose–Iodine Complex: Helix-coil Transmission and Electronic Conductivity of the (W. L. Peticolas), 898
Anaesthetic: Propylene Phenoxetol as a Fish (T. B. Bagenal), 1222
Analysis of Partial Glyceride Mixtures (R. A. Brett), 484
Analytical Chemistry. Vol. 2 (edited by Carl E. Crouthamel) (Progress in Nuclear Energy, Series 9), *review* by D. I. Coomber, 325
  Treatise on, Part 2, Vol. 7 (edited by I. M. Kolthoff and Philip J. Elving), *review* by Prof. R. Belcher, 832
Anaphylactic Sensitization with Cancer Chemotherapy Drugs: Role of Species Specificity in Failure of Inhibition of Guinea Pig (H. I. Maibach and Henry G. Maguire), 82
Anatomy: Lectures on the Whole of (William Harvey). An annotated translation of "Prelectiones Anatomiae Universalis" (Prof. C. D. O'Malley, *et al.*), *review* by Sir Russell Brock, 523
Anbar, M., and M. Inbar: Effect of Thyroid Irradiation on the Release of Labelled Protein-bound Iodine in Rats, 302
Andaman Islands: Pigmy Tools from the (P. C. Dutta), 624
Anderson, A. J., *et al.*: Glycoprotein Excretion following the Injection of Papain into Rabbits, 707
Anderson, J. H., *et al.*: Titanium Colour Centres in Rose Quartz, 246
Anderson, L. L., *et al.*: Effect of the U.S. High-altitude Nuclear Explosion on Radio Wave Propagation, 887
  Sudden Changes in Amplitude and Phase of the Very-Low-Frequency Signal from Station GBR at Salisbury, South Australia, 783
Andrade, Prof. E. N. Da C. Bath-tub Vortex, 480
  Physics for the Modern World (Science for the Modern World Series, Vol. 2), *review*, 422
Andrewartha, H. G.: Introduction to the Study of Animal Populations, *review* by Prof. V. C. Wynne-Edwards, 527
Aneuploids in Oat Varietal Populations (J. B. Hacker and R. Riley), 924
Anfinsen, Jun., C. B. *et al.* (edited by). Advances in Protein Chemistry, Vol. 15, *review* by Dr. Brian S. Hartley, 423
Ånger, B., *et al.*: Lithium Emission in Twilight at Uppsala during November 1962, 783
Angiosperms: Nature of Vestured Pits in (A. B. Wardrop, *et al.*), 202
Anglo-Belgian Company for Marine Reactor Development, 650
Angstadt, R. L., and F. R. Hurley: Hydration of the Alite Phase in Portland Cement, 688
Anguilla anguilla L. and *Pleurodeles waltlii* Mich.: Vectorcardiogram of (V. Noseda *et al.*), 816
Angyal, S. J., *et al.*: Occurrence of Configurational Inversion during Tritiation by the Wilzbach Method, 485
Anhydrite in the Recent Sediments of the Persian Gulf: Association of Dolomite and (R. Curtis, *et al.*), 679
3,6-Anhydrogalactose with the Indolyl-3-acetic Acid Reagent: Colorimetric Determination of (W. Yaphe), 488
Anhydroglucose: Stimulation of Sporulation in *Penicillium* by (J. J. Armstrong *et al.*), 723
Animal Anaesthesia: Small, Meeting to be held by the British Small Animals Veterinary Association and the Universities Federation for Animal Welfare, 652
Animal Breeding Abstracts, 30, 285; 1962, 23
Animal Dispersion in Relation to Social Behaviour (Prof. V. C. Wynne-Edwards), *review* by C. S. Elton, 634
Animal Ecology (Prof. S. Charles Kendeigh) *review* by Dr. R. H. Hedley, 328
Animal Geography (Wilma George), *review* by Dr. Maurice Burton, 3
Animal Health Trust: M. S. Moss appointed to the Forensic Laboratory, 23
Animal Health Yearbook, 1961, 22
Animal Populations: Introduction to the Study of (H. G. Andrewartha), *review* by Prof. V. C. Wynne-Edwards, 527
Animal Tissues: Effect of Light on the Oxidation of Reduced Nicotinamide–Adenine Dinucleotide Phosphate in (H. Zwarenstein and V. van der Schyff), 714
Animals, January 8, 1963, 542
Animals: Notions of Niche and Competition Among Animals, with Special Reference to Freshwater Fish (Dr. A. H Weatherley), 14, *erratum*, 1253
Animals in South Africa: Asbestosis in Non-Experimental (I. Webster), 506
Anisotropy Measurements on some Silurian Siltstones: Susceptibility (N. Hamilton), 170
Anisoyloxy Radical: A Carbon Isotope Effect in the Decarboxylation of the (T. H. Bates and J. C. Bevington), 1294
Annals of the International Geophysical Year (*I.G.Y. Solar Activity Maps, DI and DII*), (195, 1237), 1054
Annual Change in the Declination ('Variation') in Western Scandinavia and the North Sea (H. F. Finch), 67; (G. Gjellestad and H. Dalseide), 67
Annual of the British School at Athens, No. 56, 1961, *review* by Peter Warren, 117
Annual Review of Biochemistry. Vol. 31 (edited by J. M. Luck), *review* by Prof. D. C. Harrison, 526
Annual Review of Physical Chemistry, Vol. 13 (edited by H. Eyring), *review* by Prof. J. R. Partington, 632
Anodic Oxide Films on Aluminium Alloys: Electrolytic Detachment of (R. C. Spooner), 995
Anomalous Dispersion: Determination of Space-Groups using (G. N. Ramachandran and R. Parthasarathy), 70
Anomalous Infection of Mice with *Schistosoma mansoni* (Anne E. Sorrell and A Omedes), 814
Anopheles gambiae Giles: Tests for Multiple Insemination in (L. K. H. Goma), 99
Anopheles stephensi: Mating Behaviour of (M. S. Qureshi and M. Arthur), 312
Antagonistic Action of Urokinase to Bradykinin- and Plasminogen-induced Capillary Permeability (A. L. Copley and V. Tauluca), 294
Antarctica: Geographical Variations of Oxygen-18/Oxygen-16 Ratio in Surface Snow and Ice from Queen Maud Land (R. Gonfiantini *et al.*), 1096
  Sponge Spicule Pebbles at Hut Point Peninsula (H. W. Wellman), 681
  Transport of Pebbles over Smooth Ice in (W. H. Wellman), 681

Anthocyanins of the Squill (F. A. Vega and C. Martin), 382
Anthony, Dr. H. D.: History of Science: An Annual Review of Literature, Research and Teaching, Vol. I, *review*, 217
Anthrone: Reaction of Sulphoquinovose from Red-Clover Lipids with (R. O. Weenink), 62
Anthropology and Sociology: Prof. M. G. Marwick appointed to the chair of, 1253
Antibiotic Supplements: Differential Growth Response of the Male and Female Rice Moth to (D. Bhanu), 1227
Antibodies against Homologous Tissue Antigens: Demonstration of Humoral and Cellular Fixed (F. Schleiffarth *et al.*), 403
Antibodies in Serum: A Freezing–thawing Technique for Concentrating (B. A. McErlean), 507
Antibodies on the *in vitro* Uptake of 5-Hydroxytryptamine by Blood Platelets: Effect of Anti-Platelet (Dr. J. M. Bridges *et al.*), 364
Antibodies produced by New-born Rabbits. Properties of Phage-Neutralizing (B. Pernis *et al.*), 807
Antibody: Phagocytosis of *Salmonellae* by Reticuloendothelial Cells of New-born Piglets lacking Natural (D. Mouton *et al.*), 706
Antibody from Guinea Pigs: Electrophoretic Analysis of Serum and Pleuroperitoneal Fluid Proteins and (J. Benovitz *et al.*), 704
Antibody Production of Injection of an α_2-Protein Fraction: Effect of (J. F. Mowbray), 1019
Anti-*Brucella abortus* Agglutinins across the Gut in Young Mice: Transmission of (I. G. Morris), 813.
Anti-D(Rho): Bivalent Nature of Incomplete (B. Pirofsky and M. Cordova), 392
Antigen on Immunological Tolerance in Radiation Chimæras: Influence of Excess of (O. B. Zaalberg *et al.*), 300
Antigenic Relationship between Host and Parasite (Dr. J. K. Dineen), 471
Antigenicity of Synthetic Polypeptides with known Amino-acid Sequence (Prof. A. E. Axelrod, Anthony C. Trakatellis and Prof. Klaus Hofmann), 146
Antigens: Demonstration of Humoral and Cellular Fixed Antibodies against Homologous Tissue (F. Schleiffarth *et al.*), 403
Antigens in Kidney Microsomes: Enzymatic Activities of the Soluble (K. Ozato and T. S. Okada), 1310
Antihæmophilic Factor: Synthesis of Plasma (W. D. McLester and J. B. Graham), 708
Antihistaminic Action of Lysozyme (J.-L. Parrot and G. Nicot), 496
Anti-Js^{b}, the Expected Antithetical Antibody of the Sutter Blood Group System (R. H. Walker, C. I. Argall, E. A. Steane, T. T. Sasaki and T. J. Greenwalt), 295
Antiphonal Singing in Birds as Evidence for Avian Auditory Reaction Time (Dr. W. H. Thorpe), 774
Antipoliovirus Activity of Guanidine: Potentiating Effect of 5-Fluorouracil on the *in vitro* (B. Loddo *et al.*), 408
Antisera to Human Follicle-stimulating Hormone: Preparation of (W. R. Butt *et al.*), 388
Antiserum against a Particular Sub-fraction separated from Kidney Microsomes: Production of a Highly Tissue-specific (T. S. Okada and A. G. Sato), 1216
Antiserum Inhibition of the Œstrous Cycle in Normal Rats (W. P. Young, R. Nasser and T. Hayashida), 1117
Antitumour Substance from *Lampteromyces japonicus*: Isolation of Lampterol, an (K. Nakanishi *et al.*), 292
Anti-Virus Action of Azaserine–Thioguanine *in vivo* (D. H. Adams and B. M. Bowman), 316
Antlerite: Refinement of the Crystal Structure of (J. J. Finney and T. Araki), 70
Anvil device: Pressure Calibration of a Tetrahedral (R. B. Graf and B. C. Deaton), 678
Apartheid: *Science and*, 1141
Aphid Antennæ: Photokinetic Function of (C. O. Booth), 265
Apparent Molecular Weight of Insulin in Dilute Acid Solution (P. D. Jeffrey and J. H. Coates), 1104
Apple Trees: Effect of Gibberellic Acid on Flowering of (R. Marcelle and C. Sironval), 405
Appleton, Sir Edward: Ionospheric Consequences of the Earth's Orbital Eccentricity, 1239
Application of Gibberellic Acid to Strawberry Plants at Different Stages of Development (J. N. Turner), 95
Applied Geophysics U.S.S.R. (edited by Dr. Nicholas Rast), *review* by Prof. S. K. Runcorn, 524
Applied Mechanics: Eleventh International Congress to be held on, 751
Aqueous Outflow Resistance in Rabbits after Sympathetic Denervation: Supersensitivity of (M. L. Sears and T. E. Shark), 387
"Aqueous Reprocessing Chemistry of Nuclear Fuels" International Symposium organized by the European Company for Chemical Processing of Irradiated Fuels and the Organization for Economic Co-operation and Development, European Nuclear Energy Agency, 850
Aqueous Solutions: Effect of Ionizing Radiation on Adenine in Aerated and De-aerated (Miss J. J. Conlay), 555
Arabidopsis thaliana: Multiple Allelic Control of Chlorophyll *b* Level in (Y. Hirono and G. P. Rédei), 1324
Araki, T., and J. J. Finney: Refinement of the Crystal Structure of Antlerite, 70
Araucanian Indians of Chile: Types of Haptoglobins in (R. Nagel and R. Etcheverry), 187
Arcari, G., *et al.*: Progestational Activity of 4-Hydroxy-17-Alpha-Acetoxyprogesterone, 292
Archæology: S. S. Frere appointed Professor of, 1253
  H. S. Smith appointed to a readership in, 1156
Area Porosa of Ixodid Ticks: Function of the (B. Feldman-Muhsam), 100
Arendt, P. R.: Measurement of Ionospheric Electron Content Regardless of Approximations, 579
Argall, C. I., *et al.*: Anti-Js^{b}, the Expected Antithetical Antibody of the Sutter Blood Group System, 295
Argininosuccinic Acid in Germinating Seeds of *Vicia faba* L. (J. T. Barber and D. Boulter), 1112
Argon: Oxidation of Plutonium in Moist Air and (J. B. Raynor and J. F. Sackman), 587
Argon-39 in the Potassium–Argon Method of Age Determination: Possible use of (Prof. John H. Naughton), 661
Argonne National Laboratory: Chemistry Division Symposium to be held on "The Transplutonium Elements", 236
  Conference on "Inert Gas Compounds" will be held in April 1963, 955
Arbutin–Hydroquinone in Pear Blossoms to Invasion by *E. amylovora*: Relation of (D. C. Hildebrand and M. N. Schroth), 513
Arias, I. M., *et al.*: Glucuronide Formation and Transport of Various Compounds by Gunn Rat Intestine *in vitro*, 1109
Arid Conditions: Environmental Physiology and Psychology in (Dr. C. S. Leithead), 1057
Armillaria mellea: an Ozonophilic Basidiomycete (Martha D. Berliner), 309
Armstrong, D. A. J., and G. L. Mills: Chemical Characterization of Kinins of Human Plasma, 490
Armstrong, J. J., *et al.*: Stimulation of Sporulation in *Penicillium* by Anhydroglucose, 723
Arnold, Prof. A. H. M.: Transient Circuit Analysis, *review*, 422
Arnold, W. N., *et al.*: Sensitive Qualitative Test for Sulphoxides on Paper Chromatograms, 380
Arnott, Dr. Struther: International Tables for X-ray Crystallography, Vol. 3, *review*, 326
Aromatic Hydrocarbons: Origin of the Phosphorescence Radiation in (M. A. El-Sayed), 481
  Use of Modified 'Bentone-34' for the Gas Chromatographic Separation of (J. V. Mortimer and P. L. Gent), 789
Aronson, R. F., *et al.*: Separation of Polypeptides bound by Albumin in Human Plasma, 1009
Arsenault, G. P., and W. Yaphe: Effect of Acetaldehyde on the Resorcinol Test for Fructose, 181
Arterial Hypertension: Isolation of a Polar Aldosterone-like Substance from the Urine and Adrenal Incubates of Patients with (H. E. Carr, jun., and I. Nauklarinen), 696
Arteriosclerotic Rats: Blood Coagulation in (Prof. B. C. Wexler and Dr. Mar J. Epstein), 159
Arthrobacter globiformis: Nitrification by (H. B. Gunner), 1127
Arthrobotrys oligospora Fresenius: A Nematotoxin produced by the Nematophagous Fungus (Th. H. A. Olthof and R. H. Estey), 514
Arthropod-borne Viruses: Isolation from Man in Slovenia of a Virus belonging to the California Complex of (M. Likar and J. Casals), 1131
Arthur, M., and M. S. Qureshi: Mating Behaviour of *Anopheles stephensi*, 312
Asbestosis in Non-Experimental Animals in South Africa (I. Webster), 506
Ascospores in Soil: Occurrence of Dormant (J. H. Warcup and K. F. Baker), 1317
Aschaffenburg, R., and A. Sen: Comparison of the Caseins of Buffalo's and Cow's Milk, 797
Ascorbic Acid Oxidase: Spectrophotometric Assay of (M. F. Oberbacher and H. M. Vines), 1203
Asfeld, L., and D. Schwartz: Solvation of the Proton in Humic Acids, 177
Ashby, Sir Eric: Elected a Fellow of the Royal Society, 1251
Ashcroft, G. W., *et al.*: Tryptamine in the Blood and Urine of a Patient with a Carcinoid Tumour, 502
Ashford, A., *et al.*: Thymol Basic Ethers and Related Compounds: Central Nervous System Depressant Action, 969
Ashley Montagu, M. F. (edited by): Genetic Mechanisms in Human Disease: Chromosomal Aberrations, *review* by S. Muldal, 218
Ashton, Dr. E. H.: Appointed Reader in Primate Anatomy, 132
Aslib Cranfield Research Project: *Investigation into the Comparative Efficiency of Indexing Systems*, 129
Asparagine in Seedlings: Incorporation of Hydrocyanic Acid labelled with Carbon-14 into (S. Blumenthal-Goldschmidt *et al.*), 718
Aspergillus flavus and Groundnut Toxicity (P. C. Spensley), 31
Aspinall, R.: Airborne Radar (Principles of Guided Missile Design), *review*, 220
Assa, S., and Z. Laron,: Immunological Investigations of Sheep Prolactin, 299
Assay of Tritium, Carbon-14 and Sulphur-35 in Wool by Liquid-Scintillation Counting (A. M. Downes and A. R. Till), 449
Assimilation of Minerals by Higher Plants (Dr. George H. Fritz. Substance of a lecture given before the Soil and Crop Science Society, Florida), 843
Associated Electrical Industries: Scientific film, *Electron Microscopy*, awarded the Nikola Tesla gold medal, 21
  Analysis by Mass, Film, 21
Association for Programmed Learning, 953
Association of Dolomite and Anhydrite in the Recent Sediments of the Persian Gulf (R. Curtis, G. Evans, D. J. J. Kinsman and D. J. Shearman), 679
Association of the British Pharmaceutical Industry. G. E. Yates appointed Director, 749
Association of Titanium (IV) Alkoxides in Benzene (R. L. Martin and G. Winter), 687
Association of Universities of the British Commonwealth: Report for the year ended July 31, 1962, 339
Association of Universities of the British Commonwealth for the Commonwealth Education Liaison Committee. Second Annual Report of the Commonwealth Scholarship Plan for the period ended March 31, 1962, 731
Association of University Teachers (Dr. D. Chapman), 653
Assortative Mating in producing New Species (R. G. Silson), 105
Astatic Magnetometer to a Cylindrical Rock Specimen: Response of an (J. L. Roy), 134
Astbury, Dr. N. F.: Progress in Ceramic Science, Vol. 2, *review*, 932
  Science of Ceramics, Vol. 1: Proceedings of a Conference, June 1961 (edited by G. H. Steward), *review* by Dr. N. F. Astbury, 932
Astronomic and Spectronomic Instruments: Recent Developments in, 854
Astronomy in the United States, 651
Aterman, K., and S. Norkin: The Periodic Acid–Schiff Reaction, 1306
Atherton, J. G., and K. S. K. Lam: Measles Virus, 821
Atlantic Ocean: Meteorological Conditions Dependence of Radon Concentration in the Air above the (J. Fontan *et al.*), 583
Atmosphere: A Secondary Source of Water Vapour in the Upper (S. Rangarajan), 1099
  Helium Ion Belt in the Upper (Dr. S. J. Bauer), 36
  Model Experiments for Vortex Columns in the (Dr. B. R. Morton), 840
  Seasonal Variation of Turbulence in the Upper (R. G. Roper and Dr. W. G. Elford), 963
Atmospheric Gravity Waves from Nuclear Explosions: Period and Amplitude in (H. Wilgner and U. Ericsson), 994
Atom: Living with the (Prof. Ritchie Calder), *review* by G. R. Noakes, 421
Atoms: Bond Energy of Vacancies and Interstitial Atoms in Graphite (R. L. Woolley), 66
  Heterogeneous Recombination of Free (F. S. Larkin and B. A. Thrush), 375
Atoms and the Universe. An Account of Modern Views on the Structure of Matter and the Universe (Prof. G. O. Jones, Prof. J. Rotblat and G. J. Whitrow), second revised edition, *review* by Prof. E. B. Paul, 323
Atoms from the 'Best' Planes of Cholesteryl Iodide: Distances of (Dr. D. A. Norton and J. M. Ohrt), 450
Atrium of the Dog by Tyramine. Release of Catecholamines from the (W. J. Hall and J. D. Sheehan), 1116
Attempts to Isolate Infectious Nucleic Acid from Vaccinia Virus and Virus-Infected Cells (Prof. H. C. Bubel and D. A. Wolff), 867
Audio-visual Aids in Teaching and Research. Committee formed, 1154
Aurora on October 28, 1961: Photometric Observations from the Southern Hemisphere of 5577A Emission from the (C. T. Lewis), 992
Austin, Sue C., and C. M. Stewart: Soluble Components of the Cambial Zone of *Eucalyptus regnans* F. Muell., 203
Australasian Conferences on Hydraulics and Fluid Mechanics: Report of First Conference (R. Silvester), 958
Australian Polarographic Society: Formation of and Election of Officers, 751
Australopithecines: Cranial Capacity of *Zinjanthropus* and other (Prof. Phillip V. Tobias), 743

INDEX

Auto-immune Selection of Carcinoma Cells in Man (R. B. Goudie), 1020
Automatic Comparison of Finger-Ridge Patterns (Mitchell Trauring), 938
"Automatic Control": Symposium organized by the British Institution of Radio Engineers and the Institution of Electrical Engineers, 1054
Autoradiography combined with Electron Microscopy: Localization of Tritiated 'Digoxin' in the Myocardial Cells of Frogs and Dogs by (Dr. John R. Smith and Dr. Harry A. Fozzard), 562
Autotransplantation on Growth of the Methylcholanthrene Sarcoma in Rats and Mice: Ineffectiveness of (M. Matsuyama *et al.*), 805
Auxin: Sources of Error in the Wheat Cylinder Bioassay for (Dr. K. E. Cockshull and Prof. O. V. S. Heath), 362
Aves, E. K., *et al.*: Quantitative Histochemistry of Succinate Dehydrogenase in Tissue Sections, 568
Avian and Human Metabolic Activity in Relation to the Daylight/Darkness Ratio: Seasonal Variations of (D. R. Barber), 776
Avian Auditory Reaction Time: Antiphonal Singing in Birds as Evidence for (Dr. W. H. Thorpe), 774
Avian Erythroblastosis: Iron Metabolism in (C. Le Q. Darcel *et al.*), 1299
Avrameas, S., and G. Broun: Visualization of Different Diphospho- and Triphosphopyridine Nucleotide Dehydrogenase Isozymes on an Agar-gel Plate, 1208
Axelrod, Prof. A. E.: Antigenicity of Synthetic Polypeptides with known Amino-Acid Sequence, 146
Axenic Culture in Two Trichomycetes from Californian Mosquitoes (Truman B. Clark, William R. Kellen and James E. Lindegren), 208
Axial Period of Fibrinogen and Fibrin (L. Stryer, C. Cohen and R. Langridge), 793
Axon, H. J.: Destruction of the Widmanstatten Structure in Iron Meteorites by Laboratory Heat-Treatment, 1291
Aynedjian, Hagop S., and Norman Bank: Measurements of Tubular Fluid pH *in vivo* in Rats, 185
Azaserine–Thioguanine *in vivo*: An Anti-Virus Action of (D. H. Adams and B. M. Bowman), 316
Azimuth: Radio-Transit Telescopes steerable in (P. D. Usher), 170
Azo Dye Liver Carcinogenesis: Reaction of Hydroxymethylaminoazobenzene with Nucleic Acids *in vitro* (J. J. Roberts and G. P. Warwick), 87
Azuma, T., *et al.*: Fractionation Phenomena in Highly Radioactive Fall-Out Particles, 964

BAČESCU, Mihai C., *et al.*: Abyssal Crustacea, *review* by Dr. Isabella Gordon, 217
Bachelard, Dr. H. S., *et al.*: Interrelationship between Glucose Utilization of Brain and Heart, 869
Bacillus subtilis: Replacement of Thymidylic Acid by Deoxyuridylic Acid in the Deoxyribonucleic Acid of a Transducing Phage for (I. Takahashi and J. Marmur), 794
Bacillus subtilis of Cell Growth: Effect of Bromouracil-labelled Transforming Deoxyribonucleic Acid of (D. L. Gimlin *et al.*), 407
Bacq, Z. M., and Peter Alexander: Fundamentals of Radiobiology, revised, second edition, *review* by Dr. E. V. Hulse, 931
Bacteria: Carbonic Anhydrase in (P. P. Veitch and L. C. Blankenship), 76
  Differences between Penicillinases from Gram-positive and Gram-negative (Dr. J. T. Smith and J. M. T. Hamilton-Miller), 976
  'Endogenous Factor' in Sporogenesis in (V. R. Srinivasan and H. O. Halvorson), 100
  Induction of Callus on Decapitated Hypocotyls of *Helianthus* by *Escherichia coli* and other (W. R. Philipson and D. E. G. Sheat), 204
Bacteria in Aqueous Suspension. Effect of Chilling on (R. E. Strange and A. G. Ness), 819
Bacterial Endosymbiote in the Protozoon *Crithidia* (*Strigomonas*) *oncopelti*: Deoxyribonucleic Acid Type attributable to a (J. Marmur *et al.*), 1228
Bacterial Growth at Low Population Densities (II) (H. W. Jannasch), 1322
Bacterial Origin of Certain Viruses: Identity of the Eaton Agent with *Streptococcus MG* (Phyllis Pease), 1132
Bacterial Photosynthesis: Transfer of Energy from Bacteriochlorophyll to a Reaction Centre during (W. J. Vredenberg and Dr. L. N. M. Duysens), 355
Bacterial Spores to Lysozyme and Hydrogen Peroxide with Reagents which Rupture Disulphide Bonds: Sensitization of (G. W. Gould and A. D. Hitchins), 622
Bacterial Transformation: an Antigen Specific for 'Competent' Pneumococci (G.-C. Nava, A. Galis and S. M. Beiser), 903
Bacteriochlorophyll to a Reaction Centre during Bacterial Photosynthesis: Transfer of Energy from (W. J. Vredenberg and Dr. L. N. M. Duysens), 355
Bacteriology: Dr. J. G. Shoesmith appointed lecturer in, 132
Bacteriophage *T4B*: Polyimines Mutagenic for (J. W. Drake), 1028
Bacteriophages: Lysogeny in *Providence* Strains and the Host-range of *Providence* (J. N. Coetzee), 515
  Physical and Chemical Properties of Two New Small (D. A. Marvin and H. Hoffmann-Berling), 517
Bade, M. L., and R. B. Clayton: Cholesterol Esters of the Cockroach *Eurycotis floridana*, 77
Badenhuizen, Prof. N. P.: Formation and Distribution of Amylose and Amylopectin in the Starch Granule, 464
Bagenal, T. B.: Propylene Phenoxetol as a Fish Anaesthetic, 1222
Baker, F. N., and G. W. Salisbury: Nuclear Size of Live and Dead Bovine Spermatozoa, 820
Baker, H., *et al.*: Blood- and Serum-levels of Water-soluble Vitamins in Man and Animals, 490
Baker, K. F., and J. H. Warcup: Occurrence of Dormant Ascospores in Soil, 1317
Baker, Prof. W.: *Obituary* of Prof. T. S. Wheeler, 1152
Balanced Polymorphism in *Dactylis glomerata* Sub-species *woronowii* (P. L. Curran), 105
Balchin, Prof. W. G. V.: Design of Water-Resource Systems: New Techniques for Relating Economic Objectives, Engineering Analysis and Governmental Planning, *review*, 323

Chemical Composition and Terminology of Specialized Organelles (Melanosomes and Melanin Granules) in Mammalian Melanocytes (Dr. M. Seiji, Prof. T. B. Fitzpatrick, R. T. Simpson and M. S. C. Birbeck), 1082
"Chemical Process Hazards with special reference to Plant Design": Symposium on, 1156

Chemical Protection for the Incorporation of Phosphorus-32 into Nucleic Acids of Lymphatic Cells against γ-Irradiation (I. Honjo, Y-T. Tchoe, Y. Takamori and M. Akaboshi), 914
Chemical Society : 1961 Corday–Morgan Medal and Prize awarded, 1052
  The Harrison Memorial Prize 1962, awarded, 436
Chemical Society of Stockholm : The Golden Scheele Medal awarded, 731
Chemical Transmission in the Central Nervous System (Dr. J. H. Gaddum), 741
Chemisorption of Oxygen by Nickel Oxide : Influence of Mercury Vapour on (H. B. Charman and R. M. Dell), 284
Chemistry : Solvent Extraction (J. M. Fletcher), 957
Chemistry and Technology of Leather, The, Vol. 3 (edited by Fred O'Flaherty, William T. Roddy and Robert M. Lollar), *review* by Dr. A. I. Scott, 635
Chemistry, Physics and Biology for the Modern World Chemistry (Prof. George Porter), Physics for the Modern World (Prof. E. N. da C. Andrade), Biology for the Modern World (Prof. C. H. Waddington), Science for the Modern World Series, Vols. 1–3, *review*, 422
Chemotaxonomie der Pflanzen (Prof. R. Hegnauer), Band 1, *review* by Dr. L. Wallicki, 627
Chester Beatty Research Institute Serial Abridged Life Tables, England and Wales 1841–1960. Part 1: Tables, Preface and Notes. Compiled by R. A. M. Case, Christine Coghill, Joyce L. Harley and Joan T. Pearson, 230
Chiasmata and Crossing-over : Interchromosome Effects of (H. K. Jain and S. L. Basak), 725
Chick Embryo : Changes in Hydroxyproline-containing Fractions in the Developing (Kari I. Kivirikko), 593
  Effect of Cortisone on Collagen Formation in the (K. I. Kivirikko), 385
Chick Embryonic Cartilage : Presence of Œstrogen Sulphokinase in (J. B. Adams), 1007
Chick Embryos Nourished by Yolk-Sac Perfusion with Calcium-low Media : Successful Development of (C. R. Grau *et al.*), 257
Chicken Tissues and Eggs : Effect of Linoleic Acid on the Deposition of Dietary-saturated Fatty Acids in (L. J. Machlin), 289
Chickens on a Graft-versus-Host Reaction : Influence of the B Blood Group-histocompatibility Locus in (L. W. Schierman and A. R. Nordskog), 511
Chieffi, G., and C. Lupo : Œstrogens and Progesterone in Ovaries of the Marine Teleost, *Conger conger*, 596
Chiesa, F., *et al.* : Vectorcardiogram of *Anguilla anguilla* L. and *Pleurodeles waltlii* Mich, 816
Child, R. G., *et al.* : Effect of a New Anticancer Agent, 1,4-Dimethyl-1,4-Diphenyl-2-Tetrazene, on a Transplantable Mammary Adenocarcinoma (72*j*) and Spontaneous Mouse Breast Tumours, 85
Chile : Forest Products in, 133
Chimaeras : Donor and Host Contribution to Splenomegaly in Homologous Mouse (I. M. Zeiss and M. Fox), 673
  Influence of Excess of Antigen on Immunological Tolerance in Radiation (O. B. Zaalberg, *et al.*), 300
Chimpanzees : Serum Transferrins in (M. Goodman *et al.*), 259 ; (M. Goodman and A. J. Riopelle), 261
Chironomus plumosus : Incorporation of Iron-59 into the Cells of Different Tissues of (M. Öktay and A. Sengun), 613
Chlorambucil with Cell Surfaces : Interaction of (J. H. Linford *et al.*), 1068
Chloranil : Interaction of Amino-Acids, Proteins and Amines with (Dr. J. B. Birks and Dr. M. A. Slifkin), 42
Chlorella vulgaris : Change of Phytol into Chlorophyll *a* in (L. Blanco *et al.*), 1219
Chlorine Hyperfine-Splittings of Several 2-Hydroxy-1,4-naphthosemiquinones : Hydrogen and (T. C. Hollocher *et al.*), 74
5-Chloro-2-cyclohexyl-1-oxo-6-sulphamoyl isoindoline : a New Diuretic (E. J. Cornish, G. E. Lee and W. R. Wragg), 1296
2-Chloroethanol on the Resistance to Boron Toxicity in Wheat Seedlings : Effect of Treatment of Seeds with (T. Miyamoto), 620
Chlorophyll *a* in *Chlorella vulgaris* : Change of Phytol into (L. Blanco *et al.*), 1219
Chlorophyll *b* Level in *Arabidopsis thaliana* : Multiple Allelic Control of (Y. Hirono and G. P. Rédei), 1324
Chlorophyll–Carotene Mixtures : Thermochemiluminescence of (W. D. Bellamy and A. G. Tweet), 482
Chloroplast Fragments : Solvent-induced Changes in the Absorbancy of Isolated (J. Aghion *et al.*), 1110
Chloroplasts : Emerson Effect in Isolated (P. M. Bishop and C. P. Whittingham), 1225
Chlorpromazine of Ulcers due to Acute Starvation in Mice : Reduction of (C. J. Pfeiffer *et al.*), 1014
Chlouverakis, C. : Adipose Tissue Lipoprotein Lipase Activity in Rats of Two Different Ages (196, 1103), *erratum*, 341
Choe, Sang : Daily Age Markings on the Shell of Cuttlefishes, 306
Choe, Sang, and Y. Ohshima : Rearing of Cuttlefishes and Squids, 307
Cholesterol Esters of the Cockroach *Eurycotis floridana* (M. L. Bade and R. B. Clayton), 77
Cholesteryl Iodide : Distances of Atoms from the 'Best' Planes of (Dr. D. A. Norton and J. M. Ohrt), 450
Cholinergic–Adrenergic Dual Action of γ-Aminobutyric Methylester on a Preparation of Toad's Sinus-Atrium (Koroku Hashimoto, S. Kumakura and Kentaro Hashimoto), 500
Cholinesterase and Glutamic Decarboxylase Levels in the Brain of the Hibernating Hamster (J. D. Robinson and R. M. Bradley), 389
Christensen, Halvor N., and Dale L. Oxender : Evidence for Two Types of Mediation of Neutral Amino-Acid Transport in Ehrlich Cells, 765
Christiansen, Dr. W. N., *et al.* : Modification of the Design of the Proposed Benelux Radio Telescope, 940
Christophorou, L. G., and Dr. J. B. Birks : Excimer Formation in Polycyclic Hydrocarbons and their Derivatives, 1064
Chromatography : Separation of Radioiodine from Tellurium by Means of Column (N. Getoff and W. Parker), 278
  Separation of Zirconium and Hafnium by Reversed Phase Partition (R. H. A. Crawley), 377
Chromatography of Infective Ribonucleic Acid from Foot-and-mouth Disease Virus on Calcium Phosphate (F. Brown, J. F. E. Newman and Doreen L. Stewart), 590
Chromatography of the Gibberellins : Thin Layer (J. MacMillan and P. J. Suter), 790
Chromium-51 : Gross Structure of Hæmoglobin A_2 and the Nature of its Binding to (H. A. Pearson *et al.*), 472
Chromosomal Dynamics of *Gastrimargus* (M. R. Rajasekarasetty), 622
Chromosome : Evidence that the Xg Blood Group Genes are on the Short Arm of the X (J. Lindsten *et al.*), 648
Chromosome Count Distributions with Age : Evidence for a Sex Difference : Change of Human (Patricia A. Jacobs *et al.*), 1080
Chromosome Numbers of Central and Northwest European Plant Species (Askell Love and Doris Löve), "Opera Botanica" a Societate Botanica Lundensi, Vol. 5, *review* by Dr. V. H. Heywood, 114
Chromosome Segments : Transpositions of Modulator in Maize into Divided and Undivided (Irwin M. Greenblatt and R. Alexander Brink) 412
Chromosomes : Finger-Prints, Palms and (Prof. L. S. Penrose), 933
X-Chromosomes of an XXXXY Male : Synthesis of Deoxyribonucleic Acid on (Janet Rowley *et al.*), 251
Chromotropic Acid Chelate : Uranium (VI)- (S. K. Banerji and A. K. Dey), 1002
Chu, Prof. Ju Chin : To lecture on "The Role of Chemical Engineering in the Space Age", 23
Chuang, Lien-Sheng and Tsong-Jen Lee : Fading of Latent Image in Japanese Fuji *ET-7A* and *ET-6B* Nuclear Emulsions, 1288
Churchill, A. E. : Intranuclear Inclusions produced by Bovine *para*-Influenza, 409
Ciba Foundation Symposium on Transplantation (edited by G. E. W. Wolstenholme and Margaret P. Cameron), *review* by W. J. Dempster, 1237
Cigarette Components : Differential Responses of *Paramecium aurelia* to (Prof. Harry Wang), 946
Ciguatera Toxicity in Fish through Diet : Experimental Induction of (P. Helfrich and A. H. Banner), 1025
Cinader, B., and S. Dubiski : New Allotypic Specificity in the Mouse (MuA2), 705
Cinnoline : Molecular Addition Compounds of Polycyclic Derivatives of (J. F. Corbett), 177
Circadian Adrenal Cycle in C Mice kept without Food and Water for a Day and a Half (J. H. Galicich, F. Halberg and L. A. French), 811
Circumpolar Plants, I. Vascular Cryptogams, Conifers, Monocotyledons (Eric Hultén), Kungl. Svenska Vetenskapsakademiens Handlingar, Bd. 8, No. 5), *review* by Prof. T. G. Tutin, 1238
Cirratulus norvegicus Southern : Validity of the Species (J. D. George), 1124
Cistrons : Viruses, Genes and (Prof. C. C. Lindegren), 566 ; (N. W. Pirie), 568
Citrase of Pathogenic and Saprophytic Fungi : Urease and (Dr. H. Seneca *et al.*), 359
City and Guilds of London Institute : Prince Philip Medal Awarded, 850
Clark, Ailsa, M. : Starfishes and their Relations, *review* by Prof. J. E. Smith, 735
Clark, B. G. : New Method of Directly measuring the Galactic Magnetic Field, 474
Clark, Truman B., *et al.* : Axenic Culture of Two Trichomycetes from Californian Mosquitoes, 208
Clarke, A. M., and Prof. J. E. Hemingway : Structure of Ripple Marks, 550
Clarke, H. G. : Appointed Research Fellow in the Department of Neurosurgery, 1156
Clarke, Dr. Robert : Zoological Expeditions, 653
Clarricoats, Dr. P. J. B. : Appointed Professor of Electronic Engineering, 952
Classification of Calderas : 'Krakatoan' and 'Glencoe' Types (Dr. G. J. H. McCall), 136
Classrooms in the Stores, 523
Clastic Quartz, Provenance and Sedimentation (Dr. J. T. Greensmith), 345
Clausen, Carla R., and Prof. Mitsuru Nakamura : Beta-Galactosidase of *Shigella sonnei*, 570
Clay : Sensitivity in Leda (Edward Penner), 347
Clay Minerals : Paper Electrochromatography of (B. L. McNeal and J. L. Young), 1132
Clays : Electric Charges and Thixotropy of (G. H. Cashen), 349
Clayson, Dr. D. B. : Biological Approaches to Cancer Chemotherapy : A Symposium held at Louvain, June 1960, *review*, 526
Clayton : The 1962 James Clayton Prize awarded, 339
Clayton, R. B., and M. L. Bade : Cholesterol Esters of the Cockroach *Eurycotis floridana*, 77
Clelland, W. J., *et al.* : Acid Leaching of Uranium and Thorium Carbides, 1200
Clem, L. W., and M. M. Sigel : Immunological Response of an Elasmobranch to Human Influenza Virus, 315
Clemow, J. : Missile Guidance (Temple Press Monographs on Rockets and Missiles), *review* by G. J. Herring, 635
Cleve, H., and U. Muller-Eberhard : Immunoelectrophoretic Studies in the β_1-Hæm-binding Globulin (Hæmopexin) in Hereditary Hæmolytic Disorders, 602
"Climatic Factors and Agricultural Productivity" Symposium to be held in University College of Wales, 438
Clinical Enzymology : Enzymes in Pathogenesis. Diagnosis and Therapy (Rudolph Abderhalden), *review* by Dr. H. Lehmann, 735
Clothier, F. W., *et al.* : Encephalomyocarditis Virus and its Ribonucleic Acid : Sedimentation Characteristics, 1177
Clouds, Rain and Rainmaking (Prof. B. J. Mason), *review* by B. C. V. Oddie, 1137
Clough Memorial Research Fund, 652
Clumping *in vivo* : Platelet (A. J. Honour and J. R. A. Mitchell), 1019
Clunie, D. M., and H. A. H. Boot : Pulsed Gaseous Maser, 173
Clunies Ross, Ian : Memoirs and Papers, with some Fragments of Autobiography, *review* by Prof. W. I. B. Beveridge, 733
Coagulation : Ion-Exchange Theory of (S. Levine and E. Matijević), 1196
Coagulation of Blood in Temperature Acclimatization (P. Griminger, H. S. Weiss and K. G. Hollands), 1118
Coal Science : Fifth International Conference on, 751
Coates, J. H., and P. D. Jeffrey : Apparent Molecular Weight of Insulin in Dilute Acid Solution, 1104
Cobalt-Amine : Influence of Polyvalent Cations on the Rate of Electro-reduction and Aquation of $Co(NH_3)_4X^{n+}$ Complexes (A. A. Vlček), 786
Coblentz Society to re-publish the Carnegie Institution Monograph No. 35, 1054
Cochran, Miss Jacqueline : Elected an Honorary Member of the International Academy of Astronautics, 650
Cockroach *Eurycotis floridana* : Cholesterol Esters of the (M. L. Bade and R. B. Clayton), 77
Cockroach Mechanoreceptor : A Linear Transfer Function underlying Impulse Frequency Modulation in a (K. M. Chapman and R. S. Smith), 699
Cockroaches exposed to Dieldrin : Insecticide Absorbed by the Central Nervous System of Susceptible and Resistant (J. W. Ray), 1226
Cockshull, Dr. K. E., and Prof. O. V. S. Heath : Sources of Error in the Wheat Cylinder Bioassay for Auxin, 362
Coding of Open and Closed Carbon Chains (M. J. E. Golay), 1003
Cœnocytic Vessel Elements in *Dioscorea alata* L. (J. J. Shah), 1125
Coenzyme A–Norepinephrine Reaction : Enzymatic Behaviour of the Product of (Sidney Roston), 75
Coenzyme-substrate Reactions, and the Role of Zinc in Alcohol Dehydrogenases : Interpretation of Inhibition Kinetics of (Dr. K. Dalziel), 462
Coetzee, J. N. : Lysogeny in *Providence* Strains and the Host-range of *Providence* Bacteriophages, 515
Coetzee, J. N., and I. J. Maré : Lysogeny in *Alcaligenes faecalis* and the Host-range of *A. faecalis* Bacteriophages, 1322
Coffee : Niacin Content of (R. F. Smith), 1321
Cohen, A. S., and W. E. Paul : Relationship of Gamma-Globulin to the Fibrils of Secondary Human Amyloid, 193
Cohen, C., *et al.* : Axial Period of Fibrinogen and Fibrin, 793
Cohen, Dr. S. : Properties of the Separated Chains of Human γ-Globulin, 253
Colcemid on Synthesis of Deoxyribonucleic Acid in the Skin of the Guinea Pig's Ear *in vitro* : Effects of Colchicine and (E. Hell and D. G. Cox), 287
Colchicine and Colcemid on Synthesis of Deoxyribonucleic Acid in the Skin of the Guinea Pig's Ear *in vitro* : Effects of (E. Hell and D. G. Cox), 287
Coles, Dr. B. R. : Title of reader in physics conferred on, 1156
Collagen and a Cellulose-like Substance in Fossil Dentine and Bone (W. A. Isaacs, K. Little, J. D. Currey and L. B. H. Tarlo), 192

INDEX

Collagen Formation in the Chick Embryo : Effect of Cortisone on (K. I. Kivirikko), 385
Collagen (Mammalian) in Deuterium Oxide : Unusual Behaviour of a (J. Bello and H. R. Bello), 77
Collagens : Presence of Phosphate-mediated Cross-linkages in Hard Tissue (A. Veis and Robert J Schlueter), 1204
College of Advanced Technology, Birmingham : Courses to be held on Metrology and Quality Control, 955
College of Aeronautics : Appointments, 132
  Chair of Experimental Fluid Mechanics Established, 233
College of Arts and Crafts, Birmingham : Course on "Gem Diamonds", 1156
Colleges of Advanced Technology : Salary Re-scaling, 651
Collin, J. E. : Ionization by Charge Transfer of Adsorbed Gases in Mass Spectrometers, 1197
Colloidal Suspension Effect of Radio-frequency Fields on the Zeta-potential of a (J. H. Heller et *al*.), 997
Colombo Plan : Report for 1961–62 of the Council for Technical Co-operation in South and South-East Asia, Colombo, October 1962, 215, 237
Colonial Office : *The Colonial Territories*, 1961–1962 (Cmnd. 1751), 752
Colorimetric Determination of 3,6-Anhydrogalactose with the Indolyl-3-acetic Acid Reagent (W. Yaphe), 488
Colorimetric Method for the Quantitative Measurement of Total Lipids in Tissues (R. P. Dales), 1120
"Colorimetry of Near Whites" : Symposium on, 1253
Colour and Life (W. B. Broughton), 428
Colour Group (Great Britain) : Symposium on "Colorimetry of Near Whites", 1253
Colouring Matters and Related Fields · Recent Progress in the Chemistry of Natural and Synthetic (edited by T. S. Gore et *al*), *review* by Dr. R. Livingstone, 1237
Combination Analysis of Rabbit Serum Proteins, using High-resolution Porath Zone Electrophoresis and Starch-gel Electrophoresis (W. A. Hemmings and R. E. Jones), 695
Combined Microphoresis–Autoradiography Technique (J. L. Sirlin and J.-E Edstrom), 89
Combustion Institute, Committee of the British Section of the : Colloquium on "Electrical Properties of Flames", 955
  Tenth International Symposium to be held on "Combustion", 132
Cometary Collisions and Tektites (Prof. Harold C Urey), 228
Commination of Crystal Nucleation by a Precipitation Method (T. Adamski), 894
Comminution . a Modified Logistic Growth Function (C. C. Harris), 371
Common Pathway for Uptake of Glycine and Proline in Various Living Cells (D. F Evered and H G. Randall), 386
Commonwealth Economy . Geological Aspects of (M. J Wilson), 544
Commonwealth Education Conference : The Second, 752
Commonwealth Scholarship Commission, third Annual Report. 749
Commonwealth Scholarship Plan : Second Annual Report, 731
Commonwealth Scholarships (Amendment) Bill, 731, 749, 752, 848
Commonwealth Scientific and Industrial Research Organization Food Preservation Division Annual Report 1961–62, 235
Communication : An Experiment in Scientific (Dr. Alma Howard), 221
Compaction of Buried Sands (I J. Smalley), 966
Comparative Administration Trust : Courses in Administration and Management of Research and Development, 23
Comparative Quantitative Morphology of the Mammalian Lung Diffusing Area (Prof. S M. Tenney and J E Remmers), 54
Comparison of the Caseins of Buffalo's and Cow's Milk (R. Aschaffenburg and A. Sen), 797
Comparison of the Plasma Proteins of *C_3H* Strain Mice, found by Cellulose-Acetate and Starch-Gel Electrophoresis (E J. Duke), 288
Complement Fixation : Qualitative Differences in the Mechanism of (F. Peetoom et *al*.), 911
Complex Formation between Lead(II) Ions and Acetate Ions (Sylvia Gobom), 283
Complexes of Ferric Ion with Salicylic Acid and Related Substances (M. V. Park), 283
Composition of Normal and Pathological Cutaneous Elastin (J. G. Smith, jun , E A. Davidson and R. L Hill), 1108
Composition of the Myristicin Fraction from Oil of Nutmeg (A. T. Shulgin), 379
Comprehensive Biochemistry (edited by Prof Marcel Florkin and Prof. Elmer H. Stotz), Vol. 2, *review* by Dr D. T Elmore, 736
Computers as Botanists (Prof. W. T. Williams), (Substance of a Discourse delivered at the Royal Institution, October 1962), 1047
Concentration of Carbon Dioxide inside Leaves (D N. Moss and S. L. Rawlins), 1320
Concentration of Nicotinamide Adenine Dinucleotide in Carrageenin-induced Proliferation (M. Luscombe), 691
Concept of Multiple Molecular Forms of Lactic Dehydrogenase (Dr. N. Ressler, J. L. Schulz and R Joseph), 872
Conduction in Nucleic Acid Components (D D. Eley and R. B Leslie), 898
Congenital Orotic Aciduria : Excretion of Orotic Acid and Orotidine in Heterozygotes of (M. Lotz et *al*), 194
Conger conger . Œstrogens and Progesterone in Ovaries of the Marine Teleost (C. Lupo and G. Chieffi), 596

Education and the Humanist Revolution (Sir Julian Huxley), 8
"Education and Training in Fuel Technology" : Conference on, 438
Education by Mass Media in Emergent Countries, 215, 237
Education for Management, 1962, *Management Studies in Technical Colleges*, 339
Education of Scientists and Technologists for the New Age (Substance of Dr. B. V. Bowden's Presidential Address to the Science Masters' Association), 754
Educational Services Incorporated, U.S., 956
Effect of Acetaldehyde on the Resorcinol Test for Fructose (G. P. Arsenault and W. Yaphe), 181
Effect of Adenosine Diphosphate on the Concentration of Platelets in Circulating Blood (Prof. G. V. R. Born and Dr. M. J. Cross), 974
Effect of Adrenalectomy on Histamine Metabolism in the Rat (J. M. Telford), 600
Effect of Air Drying and Dressings on the Surface of a Wound (G. D. Winter and J. T. Scales), 91
Effect of Anti-Platelet Antibodies on the *in vitro* Uptake of 5-Hydroxytryptamine by Blood Platelets (Dr. J. M. Bridges, M. Baldini, C. Fichera and W. Dameshek), 364
Effect of Bromouracil-labelled Transforming Deoxyribonucleic Acid of *Bacillus subtilis* of Cell Growth (D. L. Gimlin, E. Farquharson and F. R. Leach), 407
Effect of Carbon Tetrachloride Intoxication on the Activity of Enzymes of the Urea Cycle in the Liver of the Rat (F. Rossi and Patricia McLean), 1207
Effect of Certain Environments on the Carapace of the Freshwater Ostracod *Cypridopsis vidua* (Muller) (R. A. Reyment), 512
Effect of Chilling on Bacteria in Aqueous Suspension (R. E. Strange and A. G. Ness), 819
Effect of Cortisone on Collagen Formation in the Chick Embryo (K. I. Kivirikko), 385
Effect of Didecyldimethylammonium Bromide against Powdery Mildews and other Fungal Plant Diseases (A. H. M. Kirby, E. L. Frick, R. T. Burchill and M. H. Moore), 514
Effect of Dietary Calcium Lactate and Lactic Acid on Fæcal *Escherichia coli* Counts in Pigs (G. S. Burnett and J. Hanna), 815
Effect of Dilution of the Diet with an Indigestible Filler on Feed Intake in the Mouse (D. C. Dalton), 909
Effect of 2 : 4-Dinitrophenol on Carbon Dioxide Fixation by a *Thiobacillus* (D. P. Kelly and P. J. Syrett), 1087
Effect of an Exogenous Interferon on Experimental Influenza Virus Infection and Interferon Production in White Mice (F. Link, D. Blašković and J. Raus), 821
Effect of Fluoride Ion on the Activation of Molecular Hydrogen by Silver(I) (M. T. Beck, I. Gimesi and J. Farkas), 73
Effect of Fluoroacetate on Uptake of Yttrium-91 in Rabbits (Jill Dearnaley), 1218
Effect of Gibberellic Acid on Flowering of Apple Trees (R. Marcelle and C. Sironval), 405
Effect of Gibberellic Acid on the Production of Prodigiosin by *Serratia marcescens* (P. O. Bennett and H. D. Graham), 778
Effect of Grafting on the Incompatibility Response of *Oenothera organensis* (A. Kivilaan and Chong W. Chang), 1130
Effect of Grinding on Quartz Particles (J. H. Talbot and E. B. Kempis), 66
Effect of Hydrogen Ion on the Rates of Migration of Sodium and Potassium Ions : Possible Relationship to Magnetism (William K. George), (Simo Salminen), 1209
Effect of Hypertonic Saline Injections on the Secretion of Thyroid Hormones in Rabbits and Guinea Pigs (G. Feuer), 1176
Effect of Hypoxia on Brain Gangliosides (J. A. Lowden and Dr. L. S. Wolfe), 771
Effect of Ionizing Radiation on Adenine in Aerated and De-Aerated Aqueous Solutions (Miss J. J. Conlay), 555
Effect of Kinetin on Powdery Mildew (J. Dekker), 1027
Effect of Light on the Oxidation of Reduced Nicotinamide-Adenine Dinucleotide Phosphate in Animal Tissues (H. Zwarenstein and V. van der Schyff), 714
Effect of Linoleic Acid on the Deposition of Dietary-saturated Fatty Acids in Chicken Tissues and Eggs (L. J. Machlin), 289
Effect of Naphthalene on the Quenching of Liquid Scintillation Solutions (Horace E. Dobbs), 788
Effect of a New Anticancer Agent, 1,4-Dimethyl-1,4-Diphenyl-2-Tetrazene, on a Transplantable Mammary Adenocarcinoma (72j) and Spontaneous Mouse Breast Tumours (A. W. Vogel, A. E. Sloboda, A. S. Tomcufcik and R. G. Child), 85
Effect of Œstradiol on Spinal Cord Convulsions in Developing Rats (A. Vernadakis and P. S. Timiras), 906
Effect of Oleic Acid on the Mobility of Human Red Cells, and its Effect on Human Serum Protein Fractions (Eric Ponder and Ruth V. Ponder), 178
Effect of Posterior Pituitary Polypeptides on the Flow of Urine after Injection in Lateral Ventricle of the Brain of a Cat (B. S. Nashold, jun., E. M. Mannarino and R. R. Robinson), 293
Effect of *Pseudomonas tabaci* on the Metabolism of Starch in Tobacco Leaves (L. Lovrekovich, Z. Klement and G. L. Farkas), 917
Effect of Puromycin on the Replication of Western Equine Encephalitis and Poliomyelitis Viruses (Dr. E. Wecker), 1277
Effect of Radio-frequency Fields on the Zeta-potential of a Colloidal Suspension (J. H. Heller, D. J. Wilkins and J. F. Freeborn), 997
Effect of Reserpine on Rate of Mortality and Growth of Duck Embryos (J. van Limborgh and F. van Meenen), 615
Effect of RNA from Normal Human Bone Marrow on Leukæmic Marrow *in vivo* (Dr. S. DeCarvalho), 1077
Effect of Synthetic 'Queen Substance' (9-oxodec-*trans*-2-enoic acid) on Ovary Development of the Housefly, *Musca domestica* L. (J. K. Nayar), 923
Effect of Tetanus on the Parental Behaviour in the Rat (A. A. Fedinec), 497
Effect of Tetraethyl Ammonium Ion on the Electrical Activity of Smooth Muscle Cell (T. Suzuki, A. Nishiyama and H. Inomata), 908
Effect of Total Thyroidectomy in the Rabbit Fœtus on Fœtal Cholesterol Metabolism (J. G. Bearn and T. R. E. Pilkington), 1302
Effect of 3 5 : 3'-triiodothyroacetic Acid on the *in vitro* Oxygen Uptake of Leucocytes of Hypopituitary Patients (I. P. C. Murray and S. K. Bisset), 1209
Effect of the U.S. High-altitude Nuclear Explosion on Radio Wave Propagation (P. Rohan, L. L. Anderson and D. J. Cooke), 887
Effect of Thyroid Irradiation on the Release of Labelled Protein-bound Iodine in Rats (M. Anbar and M. Inbar), 302
Effect of Treatment of Seeds with 2-Chloroethanol on the Resistance to Boron Toxicity in Wheat Seedlings (T. Miyamoto), 620
Effect on Antibody Production of Injection of an α_1-Protein Fraction (J. F. Mowbray), 1019
Effects of Colchicine and Colchemid on Synthesis of Deoxyribonucleic Acid in the Skin of the Guinea Pig's Ear *in vitro* (E. Hell and D. G. Cox), 287
Effects of Corticosteroids on Experimental Amoebiasis (S. Teodorovic, J. W. Ingalls and L. Greenberg), 86
Effects of High Partial Pressures of Oxygen on Fungi (Prof. John Caldwell), 772
Effects of Incorporation of Iododeoxyuridine on *Escherichia coli* (Z. Lorkiewicz), 314
Effects of Intracarotid Injection of Hypertonic Saline on Spinal Reflex Excitability (M. J. Wayner, jun., D. Grimsley, S. Kahan and W. Stoller), 390
Effects of Lysergic Acid Diethylamide on the Nesting Behaviour of Male Pigeons (E. Rosen and A. Iovino), 614
Efficiency of Infective Propagules of *Rhizoctonia solani* in reducing Vigour of Strawberry Plants (S. Rich and P. M. Miller), 719
Egelstaff, Dr. P. A. : Neutron Physics. Proceedings of the Symposium held at Rensselaer Polytechnic Institute, 1961, *review*, 117
Eggers, H. J., and I. Tamm : Inhibition of *Enterovirus* Ribonucleic Acid Synthesis by 2-(α-Hydroxybenzyl)-benzimidazole, 1327
Eggs : Effect of Linoleic Acid on the Deposition of Dietary-saturated Fatty Acids in Chicken Tissues and (L. J. Machlin), 289
Egyed, Prof. L. : The Expanding Earth, 1059
Ehrlich Cells : Evidence for Two Types of Mediation of Neutral Amino-Acid Transport in (Dale L. Oxender and Halvor N. Christensen), 765
Ehrlich's Ascites Carcinoma with Streptomycin Complexes from Tumour Cells : Immunization against (W. J. Polglase), 301
Eklund, Dr. Carl R. : *Obituary* by Dr. Kaare Rodahl, 19
Elasmobranch to Human Influenza Virus : Immunological Response of an (M. M. Sigel and L. W. Clem), 315
Elastase and Thrombogenesis (Dr. D. A. Hall and Dr. Jean E. Wilkinson), 454
Elastase Production by Micro-Organisms (Dr. A. J. Sbarra, Dr. J. S. Baumstark, Dr. R. F. Gilfillan and Dr. W. A. Bardawil), 153
Elastin : Composition of Normal and Pathological Cutaneous (J. G. Smith, jun., *et al.*), 1108
  Constitution of the Cross-linkages in (S. M. Partridge *et al.*), 1297

Elastohydrodynamic Lubrication Experiment (D. Dowson and M. D. Longfield), 586
Electric Charges and Thixotropy of Clays (G. H. Cashen), 349
Electric Discharges : Synthesis of Organic Compounds by (Prof. J. Oró), 862
Electrical Breakdown in High-temperature Gases (D. W. George and H. K. Messerle), 584
Electrical Engineering : B. M. Bird appointed lecturer in, 1253
  Title of reader conferred on Dr. V. G. Welsby, 1156
  Dr. T. Williams appointed lecturer in, 132
"Electrical Properties of Flames" : Colloquium organized by the Committee of the British Section of the Combustion Institute, 955
Electrical Storage and Hydrogen Transfer between Electrodes of Palladium and Palladium Alloys (J. C. Barton, J. A. S. Green and F. A. Lewis), 1293
Electrically Stressed Metallic Surfaces in Long Gaps in Vacuum : Phenomena occurring at (R. Hawley et al.), 274
Electricity Supply : Management in (Prof. J. Greig), 239
Electrochemical Generation and Visible Spectrum of Nitrobenzene Free Radical Anion in Dimethylformamide (W. Kemula and R. Sioda), 588
Electrodes of Palladium and Palladium Alloys : Electrical Storage and Hydrogen Transfer between (J. C. Barton et al.), 1293
'Electrogenic' Active Sodium Transport in an Epithelial Membrane : Evidence for (A. Essig et al), 701
Electrolytes in Water : A Viscosity/Density Relation for Solutions of Strong (A. D. Bramhall), 967
Electrolytic Detachment of Anodic Oxide Films on Aluminium Alloys (R. C. Spooner), 995
Electron-Donating Properties of Central Sympathetic Suppressants (J. E. Lyons and J. C. Mackie), 589
Electron Donation and Acceptance by Carcinogenic Compounds (Dr. A. C. Allison and T. Nash), 758
Electron Donation and Acceptance by Carcinogenic Compounds : Polarographic Measurements of (Dr. A C. Allison et al.), 764
Electron Impact : Behaviour of *cis* and *trans* Isomers of Decaline under (P. Natalis), 284
8-MeV Electron Irradiation : Maximum Protection of Mice against (J. Shewell et al), 91
Electron Microscopic Examination of Highly Radioactive Fall-Out Particles (T. Mamuro, T. Seiyama, T. Matsunami, A. Fujita and K. Yoshikawa), 478
Electron Microscopy : Localization of Tritiated 'Digoxin' in the Myocardial Cells of Frogs and Dogs by Autoradiography combined with (Dr. John R. Smith and Dr. Harry A. Fozzard), 562
Electron Microscopy of Alzheimer's Disease : Paired Helical Filaments in (M. Kidd), 192
Electron Microscopy of Post-mortem Changes in Porcine Muscle (R. G. Cassens, E. J. Briskey and W. G. Hoekstra), 1119
Electron Microscopy of Thin Crystals : Summer school to be held in the University of Cambridge, 438
Electron Paramagnetic Resonance Spectrum of the Acetyl Radical (J. R. Morton and W. E. Falconer), 1103
Electron Spin Resonance at Very Low Temperature : Examination of Optically Excited Amino-acids by (P. Douzou et al.), 1105
Electron-Transport System in Photosynthesis of Green Plants Analysed by Sensitive Flash Photometry (Prof. H. T. Witt, Dr. A. Muller and B. Rumberg), 987
Electrons : Synthesis of Organic Compounds by High-Energy (Prof J. Oró), 971
Electrons with Thermal Energies · Affinity of Steroids for (J. E. Lovelock et al.), 249
Electrophoresis · Combination Analysis of Rabbit Serum Proteins, using High-resolution Porath Zone Electrophoresis and Starch-gel (W. A. Hemmings and R. E. Jones), 695
Electrophoretic Analysis of Serum and Pleuroperitoneal Fluid Proteins and Antibody from Guinea Pigs (J. Banovitz, R. T. Jordan and I. L. Trapani), 704
Electrophoretic Behaviour of an Aminopeptidase of Human Tissues and Serum (E. E. Smith and A. M. Rutenburg), 800
Electrophoretic Mobility of Human Tumour Cells (P. S. Vassar), 1215
Eley, Prof. D. D. : Organic Semiconductors : Proceedings of an Inter-Industry Conference, *review*, 932
Eley, Prof. D. D., and R. B. Leslie : Conduction in Nucleic Acid Components, 898
Elford, Dr. W. G., and R. G Roper : Seasonal Variation of Turbulence in the Upper Atmosphere, 963
Ellinger, the late F., and S. Katz : Isolation of a Radiation-Mortality Reducing Factor from Spleen, 397
Elliott, R. C., and Dr. J. H. Topps : Nitrogen Metabolism of African Cattle Fed Diets with an Adequate Energy, Low-Protein Content, 668

Encephalitis (Western Equine) and Poliomyelitis Viruses : Effect of Puromycin on the Replication of (Dr. E. Wecker), 1277
Encephalitogenic Factor in Experimental 'Allergic' Encephalomyelitis (E. A. Caspary and E. J. Field), 1218
Encephalitogenic Substance : Ontogenesis of Brain Thromboplastin and of (G. J. Svet-Moldavsky and M. R. Kriegshaber), 297
Encephalomyelitis : Encephalitogenic Factor in Experimental 'Allergic' (E. A. Caspary and E. J Field), 1218
Encephalomyelitis by Cytoxic Drugs · Suppression of Experimental Allergic (D. B. Calne and S. Leibowitz), 1309
Encephalomyocarditis Virus and its Ribonucleic Acid : Sedimentation Characteristics (A. T. H. Burness, A. D. Vizoso and F. W. Clothier), 1177 ; (L. Montagnier and F. K. Sanders), 1178
Encephalopathy in Mice following Inoculation of Scrapie Sheep Brain (Dr. J. A. Morris and Dr. D. C. Gajdusek), 1084
Endeavour Prizes, 955
Endocrinology : Sir Francis Knowles appointed reader in Comparative, 132
  Dr. P. L. Krohn appointed Professor of, 132
Endocrinology of Reproduction in the River Lamprey (P. J. Evennett and J. M. Dodd), 715
'Endogenous Factor' in Sporogenesis in Bacteria (V. R. Srinivasan and H. O. Halvorson), 100
Endoparasites of Frogs : Leeches as (K. H. Mann and M. J. Tyler), 1224
Endosymbiote in the Protozoon *Crithidia* (*Strigomonas*) *oncopelti* : Deoxyribonucleic Acid Type attributable to a Bacterial (J. Marmur et al), 1228
Endotoxin-like Fraction extracted from the Cells of *Candida albicans* (H. D. Isenberg, J. Allerhand and J. I. Berkman), 316
Endotoxin with Snake Venom : Failure to protect Mice against (W. W. Spink and C. K. Su), 88
Endotoxoid Preparations (Alois Nowotny), 721
Enerback, L. : Serotonin in Human Mast Cells, 610
Energy Metabolism of Ruminants (K. L. Blaxter), *review* by J. A. F. Rook, 423
Energy Utilization of Poor Quality Roughage by Water-deprived Steers (A. Rogerson), 1222
England, D. J. F., et al. : Stimulation of Sporulation in *Penicillium* by Anhydroglucose, 723
English and the Literacy of Scientists : Teachers of (Prof. R. S. Scorer), 1049
Enhanced Salt Diffusion along the Border-line of Mosaic Permselective Membranes (F. de Korosy), 685
Enhancement of the Effect of Prednisolone by 2-Methyl-1,4-naphthoquinone (Gy. Fekete, Gy. Wix and I. Domok), 291
Enterovirus Ribonucleic Acid Synthesis by 2-(α-Hydroxybenzyl)-benzimidazole : Inhibition of (H. J. Eggers and I. Tamm), 1327
Entomological Society of Canada : The First Gold Medal Awarded, 23
Entwistle, K. W., et al.. Thermogenic Effect of Stilboestrol on Ewes, 401
Environmental Control of Flowering in *Dactylis glomerata* L. (D. M. Calder), 882
Environmental Physiology and Psychology in Arid Conditions (Dr. C. S. Leithead), 1057
Enzymatic Activities of the Soluble Antigens in Kidney Microsomes (K. Ozato and T. S. Okada), 1310
Enzymatic Behaviour of the Product of Coenzyme A-Norepinephrine Reaction (Sidney Roston), 75
Enzymatic Cyclization of L-Glutamine and L-Glutaminyl Peptides (M. Messer), 1299
Enzymatic Debranching of Glycogen (M. Abdullah and W. J. Whelan), 979 ; (D. H. Brown, B. Illingworth and C. F. Cori), 980
Enzymatic Dedifferentiation of Neoplastic Cells (M. Thiery and R. G. J. Willighagen), 1312
Enzymatic Investigations of Partially Purified Hog Kallikrein (D. A. Chambers, C. Bosser, J. M. Greep and G. L. Nardi), 1300
Enzymatic Maturation of Skeletal Muscle (V. Dubowitz), 1215
Enzymatic Reduction of δ-Keto Acids to the Corresponding Optically Active Hydroxy Acids (A. Francke), 384
Enzyme Adaptation : Sensory Deprivation and Augmentation in the Examination of (T. G. Scott), 498
Enzyme Antigen : Non-immune Gel Precipitin Tests with an (J. L. Niece and J. T. Barrett), 1021
Enzyme-Coenzyme Complexes : Proton Magnetic Resonance Investigation of (Oleg Jardetzky et al.), 183
Enzyme Induction : A New Approach to the Structure of Complex Mucoproteins : Sequential (Dr. S. A. Barker et al.), 231
Enzyme Reactions with Phenolic Compounds : Effect of O-Methyltransferase on a Natural Substrate of Fruit Polyphenol Oxidase (B. J. Finkle and R. F. Nelson), 902
Enzymes during the Germination of Fungus Spores : Synthesis of (D. Gottlieb and P. G. Caltrider), 916
Enzymes in *Escherichia coli* : Specific Metabolic Repression of Induced (Dr. E. McFall and Dr. J. Mandelstam), 880
Enzymes in Soil : Uricolytic (Margaret Martin-Smith), 361
Enzymes of the Urea Cycle in the Liver of the Rat : Effect of Carbon Tetrachloride Intoxication on the Activity of (F. Rossi and Patricia McLean), 1207
Enzymology : An Introduction to Diagnostic (Dr. J. H. Wilkinson), *review* by Dr. H. Lehmann, 735
  Clinical ; Enzymes in Pathogenesis. Diagnosis and Therapy (Rudolph Abderhalden), *review* by Dr. H. Lehmann, 735
Epinephrine in the Heart of the Frog : Increase of Sodium Efflux induced by (H. G. Haas and W. Trautwein), 80
Epithelial Membrane . Evidence for 'Electrogenic' Active Sodium Transport in an (A. Essig et al.), 701
Epithelium in Whale and Shark Peripheral Nerves : Demonstration of Perineural (T. R. Shantaveerappa and G. H. Bourne), 702
Epoxidation of the Isomeric Insecticides Aldrin and Isodrin by the Adult Housefly *In vivo* : Significance of the (G T Brooks et al.), 311
2,3-Epoxy Propyl Phenyl Ether (Phenyl Glycidyl Ether) : Reaction of Phenyl Isocyanate with (D. A. Smith), 285
Epstein, Dr. M. J., and Prof. B. C. Wexler . Blood Coagulation in Arteriosclerotic Rats, 159
Equality of Velocity of Gamma-rays of Opposite Circular Polarization in a Transverse Magnetic Field (Dr. V Knapp), 659
Equine and other Sera Poliovirus Neutralizing Properties of (G. Plummer), 870
Ergonomics Research Society . Annual Conference, 1253
Ergosome : Ribosomal Aggregate Engaged in Protein Synthesis : Characterization of the (Dr. F. O. Wettstein et al.), 430
Erickson, Dr. W. C., et al. : Modification of the Design of the Proposed Benelux Radio Telescope, 940
Ericsson, U., and H. Wigner : Period and Amplitude in Atmospheric Gravity Waves from Nuclear Explosions, 994
Erikson, J. L., et al. : Capsular Polysaccharide of *Klebsiella pneumoniae* Type A (Strain 1265), 899
Erwinia amylovora : Relation of Arbutin-Hydroquinone in Pear Blossoms to Invasion by (D. C. Hildebrand and M. N. Schroth), 513
Erythroblastosis : Iron Metabolism in Avian (C. Le Q. Darcel et al.), 1299
Erythrocyte Survival in Alloxan Diabetic Rat : Decreased (E. S. Younathan and H. N. Marvin), 85
Escherichia coli : Effects of Incorporation of Iododeoxyuridine on (Z. Lorkiewicz), 314
  Specific Metabolic Repression of induced Enzymes in (Dr. E. McFall and Dr. J. Mandelstam), 880
  Utilization of Amino-Acids during Metabolism in (Yukio Kameda et al), 314
Escherichia coli and other Bacteria : Induction of Callus on Decapitated Hypocotyls of *Helianthus* by (W. R. Philipson and D. E. G. Sheat), 204
Escherichia coli Counts in Pigs : Effect of Dietary Calcium Lactate and Lactate Acid on Faecal (G. S Burnett and J. Hanna), 815
Escherichia coli due to the Action of 5-Methyl Tryptophan · Accumulation of Ribonucleic Acid in (G. Turnock and D. G. Wild), 597

Escolme, A. I. : Alkyd Resin Technology, *review*, 736

Gamma-Globulin to the Fibrils of Secondary Human Amyloid : Relationship of (A. S. Cohen and W. E. Paul), 193
Gamma-ray Sterilization of Medical Utensils, 134
Gamma-rays of Opposite Circular Polarization in a Transverse Magnetic Field : Equality of Velocity of (Dr. V. Knapp), 659
Garber, Dr. S. : Appointed lecturer in Industrial Metallurgy, 1156
Garcia, H., and W. Lijinsky : Preparation of Carcinogenic Polynuclear Hydrocarbons labelled with Tritium by Wilzbach's Method, 688
Garcia-Fernandez, M. C., and J. L. R.-Candela : Stimulation of Secretion of Insulin by Adenosine-triphosphate, 1210
Garcia-Gancedo, A., et *al.* : Loss of the Hæmagglutinating Capacity of Fowl-plague Virus after Culture on HeLa Cells, 926
Gardner, F. F., and J. B. Whiteoak : Polarization on Radio Sources and Faraday Rotation Effects in the Galaxy, 1162
Gardiner, J. E. : A Radioactive Marking Ink, 414
Garmany Love, A. H. : Appointed lecturer in Medicine, 132
Garnett, J. L., et *al.* : Occurrence of Configurational Inversion during Tritiation by the Wilzbach Method, 465
Garrison, W. M., and M. Kland-English : Dehydropeptide Production in the Radiolysis of Solid Peptides : a Radiolytic Synthesis of Pyrazine Derivatives from Cyclic Dipeptides, 895
Gas Chromatographic Columns, particularly suited for Quantitative Capillary Column Analysis. A Reliable System for the Introduction of Samples to (P. Jenkins), 72
Gas Chromatographic Separation of Aromatic Hydrocarbons · Use of Modified 'Bentone-34' for the (J. V. Mortimer and P. L. Gent), 789
Gas Chromatography : Micro-packed Columns for (H. V. Carter), 684
  Sensitive Ionization System for the Detection of Permanent Gases and Organic Vapours by (S. R. Lipsky and M. M. Shahin), 625
  Thin-Layer Graphited Carbon Black as the Stationary Phase for Capillary Columns in (I. Halász and C. Horváth), 71
Gas Chromatography by Molecular Sieve Floor : Improved Efficiency in (Karl J. Bombaugh), 1102
Gas Compounds : Inert (Conference will be held in April, 1963, at the Argonne National Laboratory), 751, 955
Gascoigne, Dr. S. C. B. : Towards a Southern Commonwealth Observatory, 1240
Gascon, A., et *al.* : Histamine-liberating Effect of Magnesium Deficiency in the Rat, 501
Gases : Electrical Breakdown in High-temperature (D. W. George and H. K. Messerle), 584
Gases and Organic Vapours by Gas Chromatography : Sensitive Ionization System for the Detection of Permanent (S. R. Lipsky and M. M. Shahin), 625
Gases evolved from Steel in Vacuum Extraction at 600° C : Hydrocarbons in the (K. Sachs and M. Odgers), 373
Gases in Mass Spectrometers : Ionization by Charge Transfer of Adsorbed (J. E. Collin), 1197
Gass, G. H., et *al.* : Reduction by Chlorpromazine of Ulcers due to Acute Starvation in Mice, 1014
Gastric Mucosal Potential Difference : Source of the (J. G. Forte et *al.*), 874
Gastrimargus : Chromosomal Dynamics of (M. R. Rajasekarasetty), 622
Gastropod *Lymnaea stagnalis* L. : Accumulation of Radium-226 by the Freshwater (O. Van der Borght), 612
Gates, David M., et *al.* : Measurement of Moisture Boundary Layers and Leaf Transpiration with a Microwave Refractometer, 1070
Gawron, Prof. O., et *al.* : Mechanism of the Succinic Dehydrogenase Catalysed Reaction, 1270
Gear, J. H. S., et *al.* : Nomenclature of Isolates of Virus from Trachoma and Inclusion Blennorrhœa, 26
Gel-filtration of Human Bile : A Water-soluble Lipid Complex obtained in the Macromolecular Phase by (Erik Thureborn), 1301
Gel-foam : Quantitative Technique for Uniform Tumour Implantation by Trocar in (B. Gottfried et *al.*), 1309
Gel Precipitin Tests with an Enzyme Antigen : Non-Immune (J. L. Niece and J. T. Barrett), 1021
Gelatine and Glue Research (Dr. D. A. Sutton), 1161
Geller, L. M., et *al.* · Manipulation of Salt Solution—Fresh Water Drinking Regimen and Eating Behaviour in Rats, 457
Geluk, H. W., and G. B. Paerels : Synthesis of some 3-Deoxy-heptulosonic Acids (3-Deoxy-2-keto-heptonic Acids), 379
Gemmological Association : Lecture Course and Certificate on "Gem Diamonds", 1156
Gems : Their Sources, Descriptions and Identification, Vols. I and 2 (Robert Webster), *review* by E. A. Jobbins, 424
Genes and Cistrons : Viruses (Prof. C. C. Lindegren), 566 ; (N. W. Pirie), 568
Genetic Effects of Strontium-90 injected into Male Mice (K. G. Luning, H. Frolén, A. Nelson and C. Ronnback), 304
Genetic Mechanisms in Human Disease : Chromosomal Aberrations (edited by M. F. Ashley Montagu), *review* by S. Muldal, 218
Genetics : Dr. P. M. Sheppard appointed Professor of, 20
Genetics and Evolution : Selected papers of A. H. Sturtevant. Selected and edited by E. B. Lewis, *review* by Prof. C. D. Darlington, 830
Gent, P. L., and J. V. Mortimer : Use of Modified 'Bentone-34' for the Gas Chromatographic Separation of Aromatic Hydrocarbons, 789
Geochronometry : Coral Growth and (Prof. J. W. Wells), 948
Geographical Variations of Oxygen-18/Oxygen-16 Ratio in Surface Snow and Ice from Queen Maud Land, Antarctica (R. Gonfiantini, V. Togliatti, E. Tongiorgi, W. de Breuck and E. Picciotto), 1096
Geological Aspects of Commonwealth Economy (M. J. Wilson), 544
Geological Society in the German Democratic Republic, Palæontological Section, meeting held in October, 1962, 238
Geological Society of London : Awards for 1963, 541
  Prestwich Medal Awarded, 955
Geology : R. F. Cheeney appointed Research Fellow in, 132
Geology of the Neighbourhood of Edinburgh (compiled by Dr. G. H. Mitchell and W. Mykura), 235
Geomagnetic and Palæomagnetic Evidence of Fossil Axes of Rotation of the Earth (Dr. K. M. Creer), 122
Geomagnetic Field during the Miocene Period in South-Eastern Oregon : Behaviour of the (N. D. Watkins), 126
Geometrically Complicated Monogenetic Flow Folds (E. Williams), 68
Geophysics : Fundamental Problems in Turbulence and Their Relation to, Proceedings of a Symposium held in France, September 1961 (edited by Francois N. Frenkiel), *review* by Prof. S K Runcorn, 524
Geophysics U.S.S.R. : Applied (edited by Dr. Nicholas Rast), *review* by Prof. S. K. Runcorn, 524
George, D. W., and H. K. Messerle : Electrical Breakdown in High-temperature Gases, 584
George, J. D. : Validity of the Species *Cirratulus norvegicus* Southern, 1124
George, Prof. T. N. : Elected a Fellow of the Royal Society, 1251
George, William K. : Effect of Hydrogen Ion on the Rates of Migration of Sodium and Potassium Ions : Possible Relationship to Magnetism, 1209
George, Wilma : Animal Geography, *review* by Dr. Maurice Burton, 3
Georgiev, G., et *al.* : Identification of Early Labelled Products of CO_2-Fixation by Hydrogen Bacteria accumulating Poly-β-hydroxybutyric Acid, 313
Germinating Seeds of *Vicia faba* L. : Argininosuccinic Acid in (J. T. Barber and D. Boulter), 1112
Germination of Basidiospores and Production of Fructifications of Members of the Agaric Family Bolbitiaceae using Herbarium Material (R. Watling), 717
Germplasm-transmitted Alteration of Histocompatibility in the Progeny of Homograft Tolerant Mice (R. D. Guttmann and J. Bradley Aust), 1220
Gerolt, P. : Influence of Relative Humidity on the Uptake of Insecticides from Residual Films, 721
Gerontology : National Institutes of Health, 22

Humic Acids : Solvation of the Proton in (D. Schwartz and L. Asfeld), 177

Humidity and Moisture—Measurement and Control in Science and Industry : International Symposium on, 751

Humoral and Cellular Fixed Antibodies against Homologous Tissue Antigens : Demonstration of (F. Scheiffarth et *al.*), 403

Humphrey, Dr. J. H. : Elected a Fellow of the Royal Society, 1251

Hunger on Olfactory Acuity : Influence of (H. W. Berg et *al.*), 108

Hunt, Dr. J. N. : The Sea : Ideas and Observations on Progress in the Study of the Seas, *review* 421

Hurley, F. R, and R. L. Angstadt : Hydration of the Alite Phase in Portland Cement, 688

Husserl, Edmund : Phänomenologische Psychologie (Herausgegeben von Walter Biemel) Husserliana, Band 9, *review* by F. I. G. Rawlins, 419

Husson, F., and Vittorio Luzzati : Structure of Red-Cell Ghosts and the Effect of Saponin Treatment, 822

Huxley, Sir Julian : Education and the Humanist Revolution (Substance of the Ninth Fawley Foundation Lecture delivered at the University of Southampton), 8

Hydration of the Alite Phase in Portland Cement (R. L. Angstadt and F. R Hurley), 688

Hydraulics and Fluid Mechanics (R. Silvester), 958

Hydrazines on Serotonin Metabolism : Variable Action of Monoamine Oxidase-inhibiting (E Kirberger), 1211

Hydrocarbons and their Derivatives : Excimer Formation in Polycyclic (Dr. J. B. Birks and L. G. Christophorou), 1064

Hydrocarbons in the Gases evolved from Steel in Vacuum Extraction at 600° C (K. Sachs and M. Odgers), 373

Hydrocarbons in Tobacco Smoke : Precursors of Carcinogenic (Dr. E. Gil-Av and Dr. J. Shabtai), 1065

Hydrocyanic Acid labelled with Carbon-14 into Asparagine in Seedlings : Incorporation of (S. Blumenthal-Goldschmidt et *al.*), 718

Hydrogen : Effect of Fluoride Ion on the Activation of Molecular Hydrogen by Silver(I), (M. T. Beck et *al.*), 73

Hydrogen and Chlorine Hyperfine Splittings of Several 2-Hydroxy-1,4-naphthosemiquinones (T. C. Hollocher, N. M. Tooney and R. Adman), 74

Hydrogen Bacteria accumulating Poly-β-hydroxybutyric Acid : Identification of Early Labelled Products of CO_2-Fixation by (P. Hirsch et *al.*), 313

Hydrogen Ion on the Rates of Migration of Sodium and Potassium Ions : Possible Relationship to Magnetism : Effect of (William K. George) ; (Simo Salminen), 1209

Hydrogen Ions : Polarographic Behaviour of the Hexa-amminechromium(III) Ion : Role of (N. Tanaka and G. Satô), 176

Hydrogen/Oxygen : Luminescence from the H—O_2 Reaction (R. N. Dixon and B. F. Mason), 1198

Hydrogen Peroxide with Reagents which Rupture Disulphide Bonds : Sensitization of Bacterial Spores to Lysozyme and (G. W. Gould and A. D. Hitchins), 622

Hydrogen Transfer between Electrodes of Palladium and Palladium Alloys : Electrical Storage and (J. C. Barton et *al.*), 1293

Hydroxy Acids : Enzymatic Reduction of δ-Keto Acids to the Corresponding Optically Active (A. Francke), 384

4-Hydroxy-17-Alpha-Acetoxyprogesterone : Progestational Activity of (G. Arcari et *al.*), 292

2-Hydroxy-1,4-naphthosemiquinones : Hydrogen and Chlorine Hyperfine Splittings of Several (T. C. Hollocher et *al.*), 74

γ-Hydroxyarginine in Plants : Occurrence of (E. A. Bell and A. S. L. Tirimanna), 901

β-Hydroxyaspartate Pathway : A New Route for Biosyntheses from Glyoxylate (Prof. H. L. Kornberg and Dr. J. G. Morris), 456

2-(α-Hydroxybenzyl)-benzimidazole : Inhibition of *Enterovirus* Ribonucleic Acid Synthesis by (H. J. Eggers and I. Tamm), 1327

Hydroxy-cinnamic Acids and Soil Moisture Stress : Tissue (W. A. Gortner), 1316

6β-Hydroxycortisol (4-pregnane-$6\beta,11\beta,17\alpha$,21-tetrol-3-20 dione) in Liquor Amnii (M. Lambert and G. W. Pennington), 391

Hydroxymethylaminoazobenzene with Nucleic Acids *in vitro* : Azo Dye Liver Carcinogenesis : Reaction of (J. J. Roberts and G. P. Warwick), 87

Hydroxyproline-containing Fractions in the Developing Chick Embryo : Changes in (Karl I. Kivirikko), 593

5-Hydroxytryptamine by Blood Plates : Effect of Anti-Platelet Antibodies on the *in vitro* Uptake of (Dr. J. M. Bridges et *al.*), 364

Hypercritical Aerosol (M. M. Benarie), 486

Hypergammaglobulinaemia in Mink initiated by a Cell-free Filtrate (James B. Henson, John R. Gorham and Robert W. Leader), 206

Hypersensitivity to Conjugated Serum Albumin during Immune Paralysis induced in Guinea Pig by Heterologous Proteins. Repression of Delayed (T. Neveu et *al.*), 1023

Hypertension : Isolation of a Polar Aldosterone-like Substance from the Urine and Adrenal Incubates of Patients with Arterial (H. E. Carr, jun., and I. Naukkarinen), 696

Hypertonic Saline on Spinal Reflex Excitability : Effects of Intracarotid Injection of (M. J. Wayner, jun., et *al.*), 390

Hypochromism : Polarizability Theories of Polynucleotide (H. De Voe), 1295 ; (J. J. Weiss), 1296

Hypogastric Nerve of the Dog (Marthe Vogt), 804

Hypohaptoglobinaemia in an American Negro Family (A. J. Gottlieb, J. Ross, M. Greenberg and N. Wiech), 1214

Hypopituitary Patients : Effects of 3 : 5 : 3′-triiodothyroacetic Acid on the *in vitro* Oxygen Uptake of Leucocytes of (I. P. C. Murray and S. K. Bisset), 1209

Hypothyroid Mice : Diminution of Imipramine Mortality in (A. J. Prange, jun., et *al.*), 1212

Hypotonic Media : Spiralization in Tails of Mammalian Spermatozoa in (L. O. Drevius), 1123

Hypoxia on Brain Gangliosides : Effect of (J. A. Lowden and Dr. L. S. Wolfe), 771

IBERS, J. A. : Crystal and Molecular Structure of Titanium (IV) Ethoxide, 686

Ibsen, K. H., et *al.* : Utilization of Proline during Healing of Fractures, 803

Ice : Nature of Orientational Defects in (Prof. J. D. Dunitz), 860

Ice from Queen Maud Land, Antarctica : Geographical Variations of Oxygen-18/Oxygen-16 Ratio in Surface Snow and (R. Gonfiantini et *al.*), 1096

Ice in Antarctica : Transport of Pebbles over Smooth (H. W. Wellman), 681

Ice Nucleus Concentrations : A Lunar Influence on (E. K. Bigg), 172

Ichikawa, R., and M. Eto : Increase of Strontium-90 and Caesium-137 in Japanese Leafy Vegetables due to the Russian Nuclear Tests, 1961, 509

Idea of Prehistory, The (Dr. Glyn Daniel), *review* by C. A. Ralegh Radford, 420

Identification of an Organ Specific Lipid Hapten in Brain (Dr. Seymour Joffe, Prof. Maurice M. Rapport and Dr. Liselotte Graf), 60

Identification of Early Labelled Products of CO_2-Fixation by Hydrogen Bacteria accumulating Poly-β-hydroxybutyric Acid (P. Hirsch, G. Georgiev and H. G. Schlegel), 313

Identification of Soil-fertilizer Reaction Products in a Calcareous Saskatchewan Soil by Infra-red Absorption Analysis (J. D. Beaton, T. L. Charlton and R. Speer), 1329

Ignimbrites : Nature of Glass in New Zealand (R. C. Martin and J. F. Lewis), 116

Ikuma, H., and K. V. Thimann : Activity of Gibberellin 'D' on the Germination of Photosensitive Lettuce Seeds, 1313

Illingworth, B., et *al.* : Enzymatic Debranching of Glycogen, 980

Illusion for Movement perceived tactually : A Vertical-Horizontal (D. Liddle and B. M. Foss), 108

Imipramine Mortality in Hypothyroid Mice : Diminution of (A. J. Prange, jun., et *al.*), 1212

Immunization against Ehrlich's Ascites Carcinoma with Streptomycin Complexes from Tumour Cells (W. J. Polglase), 301

Immunoelectrophoretic Characterization of Proteolytic Enzymes (V. Raunio and O. Gabriel), 1012

Immunoelectrophoretic Studies of the β_1-Haem-binding Globulin (Haemopexin) in Hereditary Haemolytic Disorders (U. Muller-Eberhard and H. Cleve), 602

Immunogenic Activity of the Larval Stages of *Haemonchus placei* (J. G. Ross), 1221

Immunological Aspects of Parasitism (Dr. J. K. Dineen), 268

Immunological Investigations of Sheep Prolactin (Z. Laron and S. Assa), 299

Immunological Response of an Elasmobranch to Human Influenza Virus (M. M. Sigel and L. W. Clem), 315

Immunological Tolerance in Radiation Chimaeras : Influence of Excess of Antigen on (O. B. Zaalberg et *al.*), 300

Impacts on the Earth and Moon (G. S. Hawkins), 781

Imperial Chemical Industries Research Fellowships, 1156

Imperial College of Science and Technology : Appointments, 541

  Prof. C. D. Buchanan appointed to the Chair of Transport, 1153

  Code of Practice against Radiation Hazards (fourth edition), 849

  A Decade of Expansion : 1953–1963, *Imperial College*, 849

  Fifty-fifth Annual Report, 1961–62, 1057

  Sierra Leone Expedition 1963 (P. Rogers), 1256

Improved Efficiency in Gas Chromatography by Molecular Sieve Flour (Karl J. Bombaugh), 1102

Improved Recoveries of Protein from a Starch-'Pevikon C-870' Gel (V. Bocci), 491

Impulse Breakdown : Growth of Positive Channels in Non-uniform Fields during (G. M. Petropoulos), 174

Impulse Corona and the Pre-Breakdown Mechanism of Long Sparks (Dr. J. J. Kritzinger), 1165

In vitro Abnormality of the Blood in Von Willebrand's Disease correctable by Normal Plasma (Marjorie B. Zucker), 601

In vitro Measurements of Oxygen Consumption of Human Heart Muscle (J. N. Norman, T. A. Douglas, G. Smith and C. Henderson), 802

In vitro Species (or Type) Transformation among Strains of *Brucella* (M. Moreira-Jacob), 406

In vivo, Extracellular, Collagen Fibrillogenesis (R. Ross and E. P. Benditt), 395

In vivo study of cell Kinetics in Acute Leukaemia (Dr. A. M. Mauer and V. Fisher), 574

Inactivation of Thrombin by Normal Human Urine (H. A. Gaertner, J. Lisiewicz, H. Sieroslawski and E. Szirmai), 188

Inada, T., et *al.* : Neutron Capture in the Samarium Isotopes and the Formation of the Elements of the Solar System, 369

Inbar, M., and N. Anbar : Effect of Thyroid Irradiation on the Release of Labelled Protein-bound Iodine in Rats, 302

Incomes Policy and the Professional Employee (National Union of Teachers), 437

Incorporation of ^{14}C-Acetate into Scent Constituents by the Green Vegetable Bug (H. T. Gordon, D. F. Waterhouse and A. R. Gilby), 818

Incorporation of Amino-Acid by Root Nodules of *Galega officinalis* (Dr. M. H. Proctor and Esam Moustafa), 262

Incorporation of Hydrocyanic Acid labelled with Carbon-14 into Asparagine in Seedlings (S. Blumenthal-Goldschmidt, G. W. Butler and E. E. Conn), 718
Incorporation of Iron-59 into the Cells of Different Tissues of *Chironomus plumosus* (M. Oktay and A. Sengun), 613
Increase of Plant Virus Infection by Magnesium in the Presence of Phosphate (C. I. Kado), 925
Increase of Sodium Efflux induced by Epinephrine in the Heart of the Frog (H. G. Haas and W. Trautwein), 80
Increase of Strontium-90 and Cæsium-137 in Japanese Leafy Vegetables due to the Russian Nuclear Tests, 1961 (R. Ichikawa and M. Eto), 509
Increased Survival of Ultra-violet-irradiated *Shigella sonnei* by decreasing the Surface Tension (M. Nakamura and C. M. Ramage), 1028
Increased Survival-time in Dystrophic Mice treated with Methylandrostenediol Diamanthoylacetate (R. F. Borgman), 1304
Increased Tolerance of Bean Plants to Soil Drought by means of Growth-retarding Substances (A. H. Halevy and B. Kessler), 310
Increased Uptake of Mercury in Mouse Brain caused by 2,3-Dimercaptopropanol (M. Berlin and S. Ullberg), 84
Indexing Systems : Investigation into the Comparative Efficiency of, 129
Indium by Neutron Activation : Rapid Microdetermination of (M. Okada and Y. Kamemoto), 279
Indolyl-3-acetic Acid Reagent : Colorimetric Determination of 3,6-Anhydrogalactose with the (W. Yaphe), 488
Induced Arterial Oscillations of Blood Pressure as a Method for Investigating Regulation of Level of Blood Pressure (Prof. P. Rudomin and Prof. L. Macpherson), 1266
Induction of Callus on Decapitated Hypocotyls of *Helianthus* by *Escherichia coli* and other Bacteria (W. R. Philipson and D. E. G. Sheat), 204
Induction of Partial Synchrony in Mammalian Cells by Sub-culturing Procedures (Jesse E. Sisken), 104
Industrial Pest Control Association : Conference, 236
Ineffectiveness of Autotransplantation on Growth of the Methylcholanthrene Sarcoma in Rats and Mice (M. Matsuyama, A. Maekawa, H. Horikawa, K. Suzumori, K. Soga and K. Iwai), 805
Infections Resulting from a Deoxyribonucleic Acid Virus (Vaccinia) by Systemic Administration of 5-IODO-2′-Deoxyuridine : Suppression of (P. Calabresi *et al.*), 767
Inflammatory Reaction : Fungal Disease in Malayan Toads : An Acute Lethal (Dr. S. S. Dhaliwal and Dr. D. A. Griffiths), 467
Influence of 5-Bromosalicylhydroxamic Acid on Serum Cholesterol-level (A. Czyzyk and T. Urbanski), 381
Influence of Crop Residue Decomposition Products on the Germination of *Fusarium solani f. phaseoli* Chlamydospores in Soil (T. A. Toussoun, Z. A. Patrick and W. C. Snyder), 1314
Influence of excess of Antigen on Immunological Tolerance in Radiation Chimeras (O. B. Zaalberg, W. W. H. Weyzen and O. Vos), 300
Influence of Hunger on Olfactory Acuity (H. W. Berg, R. M. Pangborn, E. B. Roessler and A. D. Webb), 108
Influence of Mercury Vapour on Chemisorption of Oxygen by Nickel Oxide (H. B. Charman and R. M. Dell), 284
Influence of Polyvalent Cations on the Rate of Electro-reduction and Aquation of $Co(NH_3)_5X^{n+}$ (A. A. Vlcek), 786
Influence of Pregnancy and an Oxidized Lipid Diet on the Fatty Acid Composition of Blood and Tissues (H. Kaunitz, Ruth E. Johnson and D. G. McKay), 600
Influence of Relative Humidity on the Uptake of Insecticides from Residual Films (P. Gerolt), 721
Influence of the B Blood Group-histocompatibility Locus in Chickens on a Graft-versus-Host Reaction (L. W. Schierman and A. R. Nordskog), 511
Influence of the Œstrous Cycle and Ovariectomy on the Phospholipid Content of the Pineal Gland in the Rat (J. Zweens), 1114
Influenza Virus : Immunological Response of an Elasmobranch to Human (M. M. Sigel and L. W. Clem), 315
Influenza Virus Infection and Interferon Production in White Mice : Effect of an Exogenous Interferon on Experimental (F. Link *et al.*), 821
Information in Biology (Prof. H. Chantrenne), 27
Information Load and Discriminability (P. M. A. Rabbitt), 726
Information Systems in Current Use : Nonconventional Technical (National Science Foundation), 130
Information U.S.S.R. (Edited and Compiled by Robert Maxwell), *review* by Prof. L. Dudley Stamp, 3
Infra-red Absorption Analysis : Identification of Soil-fertilizer Reaction Products in a Calcareous Saskatchewan Soil by (J. D. Beaton *et al.*), 1329
Infra-red Spectra : Investigations of (Carnegie Institution Monograph No. 35 to be re-published by the Coblentz Society), 1054
Infra-red Spectroscopy : A Lignin Carbohydrate Bond as revealed by (H. I. Bolker), 489
Infrared Technology : Fundamentals of (Marvin R. Holter *et al.*), *review* by Prof. W. C. Price, 633
Ingalls, J. W., *et al.* : Effects of Corticosteroids on Experimental Amoebiasis, 86
Ingle, H. D., *et al.* : Nature of Vestured Pits in Angiosperms, 202
Inglis, W. G. : 'Campaniform-type' Organs in Nematodes, 618
Ingram, D. G., and R. Sasson : Production of Specific Haemagglutinins in Pigs after receiving Skin Homografts, 296
Ingram, G. : Methods of Organic Elemental Microanalysis, *review* by Prof. C. L. Wilson, 4
Inheritance of Serum Transferrins in Rhesus Monkeys (M. Goodman and R. C. Wolf), 1128
Inherited α-Lactalbumin and β-Lactoglobulin Polymorphism in Indian Zebu Cattle. Comparison of Zebu and Buffalo α-Lactalbumins (S. D. Bhattacharya, A. K. Roychoudhury, N. K. Sinha and A. Sen), 797
Inhibition of *Enterovirus* Ribonucleic Acid Synthesis by 2-(α-Hydroxybenzyl)-benzimidazole (H. J. Eggers and I. Tamm), 1327
Inhibition of Flowering in Poinsettia by Gibberellic Acid (C. G. Guttridge), 920
Inhibition of the Biological Action of Thyroid Hormones by Actinomycin *D* and Puromycin (Dr. J. R. Tata), 1167
Inhibition of Virus Multiplication by Foreign Nucleic Acid (Z. Rotem, R. A. Cox and Dr. A. Isaacs), 564
Injury : Vascular and Lymphatic Responses in (Dr. I. Carr), 1159
Ink : A Radioactive Marking (J. E. Gardiner), 414
Inlier : A Potassium/Argon Age Determination from a Lewisian (J. A. Miller *et al.*), 1095
Inomata, H., *et al.* : Effect of Tetraethyl Ammonium Ion on the Electrical Activity of Smooth Muscle Cell, 908
Inorganic Chemistry : Progress in, Vol. 3 (edited by F. Albert Cotton), *review* by Dr. I. R. Beattie, 635
Inorganic Chemistry and Radiochemistry : Advances in, Vol. 4 (edited by Prof. H. J. Emeléus and Dr. A. G. Sharpe), *review* by Dr. D. W. A. Sharp, 325
Insect, *Schistocerca gregaria* : Feeding Stimulants required by a Polyphagous (D. Goodhue), 405
Insect Taxa : Fatty Acid Characteristics of Some (J. S. Barlow), 311
Insecticide absorbed by the Central Nervous System of Susceptible and Resistant Cockroaches exposed to Dieldrin (J. W. Ray), 1226
Insecticides from Residual Films : Influence of Relative Humidity on the Uptake of (P. Gerolt), 721
Insecticides in Experimental Trap-huts : A Modified Window-trap for Assessment of Fumigant (A. Smith and D. J. Webley), 1227
Insects : Destructive and Useful (C. L. Metcalf and W. P. Flint), fourth edition, revised by Prof. R. L. Metcalf, *review* by Prof. G. C. Varley, 328
  Origin of Wings in (V. B. Wigglesworth), 97
Insects attacking *Striga* in Kenya (A. Davidson), 923
Insemination in *Anopheles gambiae* Giles : Tests for Multiple (L. K. H. Goma), 99
Institute for Medical Research, Federation of Malaya : Annual Report for 1960, 651
Institute for Northern Studies, University of Saskatchewan : First Annual Report, 1960–1961, 960
  Second Annual Report 1961–1962, 960
Institute for Operational Research : Formation of, 1153
Institute of Biology : Election of Officers, 131
  Thirteenth Annual Symposium : "Colour and Life" (W. B. Broughton), 428
Institute of Fuel : Conference on "Education and Training in Fuel Technology", 438
Institute of Mathematical Sciences, Madras : Announcement of the Niels Bohr visiting Professorship and the Ramanujam visiting Professorship, 751
Institute of Metal Finishing, the 1963 Conference, 1156
Institute of Metals : Medal Awards, 438
Institute of Personnel Management : Annual Report for 1961–62, 21
  Bibliography, 437
Institute of Physics and the Physical Society : Appointments and Awards for 1963, 541
Institute of Technology, Bradford : Course on "Nuclear Magnetic Resonance in Molecules of Moderate and High Molecular Weight", 1054
Institution of Chemical Engineers : Formation of a Committee in Ireland, 436
  Formation of a Working Party on Materials Science and Technology, 1052
  Prof. Ju Chin Chu to lecture on "The Role of Chemical Engineering in the Space Age", 23
Institution of Chemical Engineers (North Western Branch) : Symposium on "Chemical Process Hazards with special reference to Plant Design", 1156
Institution of Electrical Engineers : The Faraday Medal Awarded, 955
  The Rt. Hon. Lord Fleck elected an honorary member, 955
  Inaugural address of the President, 239
Institution of Electrical Engineers and the British Institution of Radio Engineers, Symposium on "Automatic Control", 1054
Institution of Mechanical Engineers : The 1962 James Clayton Prize awarded, 339
Insulin : A Significant Variable in the Rat Hemidiaphragm Assay of (J. Bingle), 595
Insulin by Adenosine-triphosphate : Stimulation of Secretion of (J. L. R.-Candela and M. C. Garcia-Fernandez), 1210
Insulin in Dilute Acid Solution : Apparent Molecular Weight of (P. D. Jeffrey and J. H. Coates), 1104
Insulin Secretion from the Pancreas by D-Mannoheptulose : Block of (Dr. H. G. Coore *et al.*), 1264
Insulin Secretion *in vitro* by Adenosine Triphosphate : Stimulation of (J. L. R.-Candela *et al.*), 1304
Insulin to a Muscle Cell Membrane Preparation : Binding of (Dr. P. M. Edelman *et al.*), 878
Intelligence : Studies in Individual Differences : The Search for (edited by James J. Jenkins and Donald G. Paterson), *review* by Dr. Liam Hudson, 1238
Interaction of Amino-Acids, Proteins and Amines with Chloranil (Dr. J. B. Birks and Dr. M. A. Slifkin), 42
Interaction of Amino-Acids with Riboflavin (M. A. Slifkin), 275
Interaction of Chlorambucil with Cell Surfaces (J. H. Linford, A. Froese and L. G. Israels), 1068
Interaction of Mechanisms Causing Eye and Eyelid Movement (Dr. D. W. Kennard and G. L. Smyth), 50
Interaction of Œstrogens labelled with Carbon-14 with Pyridine Nucleotide in the Presence of Peroxidase (P. H. Jellinck and Louise Irwin), 1107
Interaction of Technologies (L. Holliday) (Substance of a paper read before the British Association, meeting in Manchester), 222
Interchromosome Effects of Chiasmata and Crossing-over (H. K. Jain and S. L. Basak), 725
Intercostal Muscles of the Cat : Activity of Fusimotor Fibres Innervating Muscle Spindles in the (T. A. Sears), 1013
Interference by Ammonium Sulphate with the Estimation of Proteins by the Biuret Reaction (P. G. Stanley), 1108
Interferometry of Jovian Decametric Radio Bursts : Long Baseline (O. B. Slee and C. S. Higgins), 781
Interferon Production in White Mice : Effect of an Exogenous Interferon on Experimental Influenza Virus Infection and (F. Link *et al.*), 821
Intermodality Transfer of Specific Discriminations in the Monkey (W. A. Wilson, jun., and Olivia C. Shaffer), 107
International Academy of Astronautics : Honorary Members elected, 650
International Association of Microbiological Societies : Permanent Section for Microbiological Standardization : Proceedings of the 7th International Congress for Microbiological Standardization, London 1961 (edited by A. F. B. Standfast, D. G. Evans and B. G. F. Weitz), *review* by L. B. Quesnel, 1138
International Atomic Energy Agency : Bulletin, December 1962 (Enrico Fermi), 439
  Fellowship Programme in Nuclear Science, 954
  Film Library Established, 651
  Dr. F. T. Miles appointed Director of the Division of Reactors of the, 233
  Twentieth Anniversary of the First Nuclear Reactor, 22
International Atomic Energy Agency (S. Weintroub), 30
International Calcium Silicate Products Research Organization, formation of, 234
International Commission on Radiological Protection : Election of Officers and Members for 1962–65, 1052
International Committee on Weights and Measures (Report of the October 1962 meeting), 1055
International Fruit Juice Union : *Volatile Fruit Flavours*, 1054
International Geophysical Calendar 1963, 6
International Research and Development Co., Ltd., 529
International Tables for X-ray Crystallography (General Editor : Dame Kathleen Lonsdale), Vol. 3, *review* by Dr. Struther Arnott, 326
Interpretation of Inhibition Kinetics of Coenzyme-substrate Reactions, and the Role of Zinc in Alcohol Dehydrogenases (Dr. K. Dalziel), 462
Interrelationship between Glucose Utilization of Brain and Heart (Dr. R. Vrba, Dr. H. S. Bachelard and Dr. J. Krawczyński), 869
Interspecific Recombination in *Streptomyces* (M. Alačević), 1323
Interstitial Atoms in Graphite : Bond Energy of Vacancies and (R. L. Woolley), 66
Intertidal Zone Channel Deposits in Middle Jurassic Great Oolite Series, Southern England (Dr. G. deV. Klein), 1060
Inter-University Geological Congress, eleventh : Report by M. J. Wilson, 544

Intestinal Mucosa and *Penicillium digitatum* : Ethylene Production by Subcellular Particles from Rat Liver, Rat (Dr. G. Ram Chandra and Prof. Mary Spencer), 366
Intestinal Mucosa (Rat) during Fat Absorption : Phospholipid Composition and Turnover in (M. I. Gurr *et al.*), 79
Intestine : Transport of Potassium Ions in the Rat's (A. Gilman *et al.*), 1210
Intestine *in vitro* : Glucuronide Formation and Transport of Various Compounds by Gunn Rat (I. M. Arias *et al.*), 1109
Intracarotid Injection of Hypertonic Saline on Spinal Reflex Excitability : Effects of (M. J. Wayner, jun., *et al.*), 390
Intracerebral Pertussis Infection in Mice : Type-specific Immunity against (N. W. Preston and P. Evans), 508
Intranuclear Inclusions produced by Bovine *para*-Influenza (A. E. Churchill), 409
Intrinsic Electric Strength of Polythene (Dr. R. Cooper, C. H. Rowson and D. B. Watson), 663
Introduction to Diagnostic Enzymology (Dr. J. H. Wilkinson), *review* by Dr. H. Lehmann, 735
Introduction to Probability and Statistics (Henry L. Alder and Edward B. Roessler), *review* by W. Brass, 1138
Introduction to the Study of Animal Populations (H. G. Andrewartha), *review* by Prof. V. C. Wynne-Edwards, 527
Introductions of Exotic Fish (G. A. Prowse), 1123
Investigation of Small Cyclic Strains by Etch Pits at Dislocation Sites (Alwyn H. King), 664
Investigation of the Radio Source 3C 273 by the Method of Lunar Occultations (C. Hazard, M. B. Mackey and A. J. Shimmins), 1037
Investigations of the Upper Ionosphere Deduced from Top-side Sounder Data (J. W. King), 639
Iodine (^{127}I → ^{128}I) : Activation Analysis of Paper Chromatograms for (A. Dimitriadou *et al.*), 446
Iodine Complex : Helix-coil Transmission and Electronic Conductivity of the Amylose– (W. L. Peticolas), 898
Iodine in Rats : Effect of Thyroid Irradiation on the Release of Labelled Protein-bound (M. Anbar and M. Inbar), 302
Iodine-127 Iodotyrosines in Extracts of Normal Human Serum : Presence of (Prof. S. C. Werner and Dr. I. Radichevich), 877
Iododeoxyuridine on *Escherichia coli* : Effects of Incorporation of (Z. Lorkiewicz), 314
Iodotyrosines in Extracts of Normal Human Serum : Presence of Iodine-127 (Prof. S. C. Werner and Dr. I. Radichevich), 877
Ion-Exchange Theory of Coagulation (S. Levine and E. Matijević), 1196
Ionic Surfactants : Breaking Foams produced by (F. Sebba), 1195
Ionization by Charge Transfer of Adsorbed Gases in Mass Spectrometers (J. E. Collin), 1197
Ionizing Radiation on Adenine in Aerated and De-aerated Aqueous Solutions : Effect of (Miss J. J. Conlay), 555
Ionosphere : Motion of Current Systems in the (J. A. Lawrie and A. T. Price), 581
Ionosphere by Radio Pulses from a Satellite : Some Preliminary Results of Sounding of the Top Side of the (E. S. Warren), 636
Ionosphere Deduced from Top-side Sounder Data : Investigations of the Upper (J. W. King), 639
Ionospheric Consequences of the Earth's Orbital Eccentricity (Sir Edward Appleton), 1239
Ionospheric Electron Content Regardless of Approximations : Measurement of (P. R. Arendt), 579
Ionospheric Propagation Topics : *Bibliography on Direction Finding and Related* (National Bureau of Standards Technical Note, 127), 651
Ionospheric Top-side Sounder : Some Preliminary Results of Sounding of the Top Side of the Ionosphere by Radio Pulses from a Satellite (E. S. Warren), 636 ; Investigations of the Upper Ionosphere Deduced from Top-side Sounder Data (J. W. King), 639 ; Some Early Results from the Ionospheric Top-side Sounder Satellite (R. W. Knecht and T. E. van Zandt), 641
Ionospheric Top-side Sounder Satellite : Some Early Results from the (R. W. Knecht and T. E. van Zandt), 641
Iosifides, I., and G. Rabotti : Factors modifying the Post-Radiation Effects of Homologous Spleen, 199

  Circadian Adrenal Cycle in C Mice kept without Food and Water for a Day and a Half (J. H. Galicich et *al.*), 811
  Diminution of Imipramine Mortality in Hypothyroid (A J. Prange, jun., et *al.*), 1212
  Effect of an Exogenous Interferon on Experimental Influenza Virus Infection with Interferon Production in White (F. Link et *al.*), 821
  Genetic Effects of Strontium-90 injected into Male (K. G Luning et *al.*), 304
  A Germplasm-transmitted Alteration of Histocompatibility in the Progeny of Homograft Tolerant (R. D. Guttmann and J. Bradley Aust), 1220

  Ineffectiveness of Autotransplantation on Growth of the Methylcholanthrene Sarcoma in Rats and (M. Matsuyama et *al.*), 805
  Lipase and Glycerokinase Activities in the Adipose Tissue of Obese-Hyperglycaemic (Serene Lochaya et *al.*), 182
  Neurochemical Differences between two Strains of (Dr. James W. Maas), 255
  Observations by Biochemical Analysis and Autoradiography on Labelled Deoxyribonucleic Acid in the Normal and Regenerating Liver of (Dr. Finn Devik and Miss Karen Halvorsen), 148
  Protein Nutrition and Radiation Damage in (S. Tanaka et *al.*), 305
  Radiation Protection by Cyanide of both Rats and (J. Schubert and J. F. Markley), 399
  Reduction by Chlorpromazine of Ulcers due to Acute Starvation in (C. J. Pfeiffer et *al.*), 1014
  Renal Disease associated with Positive Lupus Erythematosus Tests in a Cross-bred Strain of (B. J. Helyer and J. B. Howie), 197
  Transmission of anti-*Brucella abortus* Agglutinins across the Gut in Young (I. G. Morris), 813
  Type-specific Immunity against Intracerebral Pertussis Infection in (N. W. Preston and P. Evans), 508
Mice against 8-MeV Electron Irradiation : Maximum Protection of (J. Shewell et *al.*), 91
Mice against Endotoxin with Snake Venom : Failure to protect (W. W. Spink and C. K. Su), 88
Mice by Tissue Culture Preparations of Polyoma Virus : Tumour Induction in C_3H and Swiss ICR (R. Wallace et *al.*), 298
Mice (C_3H Strain), found by Cellulose-Acetate and Starch Gel Electrophoresis : Comparison of the Plasma Proteins of (E. J. Duke), 288
Mice (Dystrophic) treated with Methylandrostenediol Dienanthoylacetate : Increased Survival-time in (R. F. Borgman), 1304
Mice following Inoculation of Scrapie Sheep Brain : Encephalopathy in (Dr. J. A. Morris and Dr. D. C. Gajdusek), 1084
Mice with *Schistosoma mansoni* : An Anomalous Infection of (Anna E. Sorell and A. Omedes), 814
Michaelis Constant : Significance of the (R. B. Fisher), 799
Micro- and Macro-Scopic Scale in the Universe : Possible Application of the Mass-Energy Cycle on a (J. L. Hughes), 441
Microanalysis : Methods of Organic Elemental (G. Ingram), *review* by Prof. C. L. Wilson, 4
Microbial Growth by Amino-Acids : Reversal of o-Nitrobenzoic Acid Inhibition of (Jerry J. Kirkland and Norman N. Durham), 210
Microbiological Standardization : Proceedings of the 7th International Congress for, London, 1961 (edited by A. F. B. Standfast, D. G. Evans and B. G. F Weitz), (International Association of Microbiological Societies : Permanent Section for Microbiological Standardization) *Review* by L. B. Quesnel, 1138
Microchemical Journal, 1252
Micro-organisms : Elastase Production by (Dr. A. J. Sbarra et *al.*), 153
Micro-packed Columns for Gas Chromatography (H. V. Carter), 684
Microphoresis-Autoradiography Technique : A Combined (J. L. Sirlin and J.-E. Edstrom), 89
Microscopy : Determination of Distribution of Water in Wheat Grains by Interference (F. Ruch et *al.*), 1318
Microsomal L-Gulonolactone Dehydrogenase (N. C. Kar, N. C. Ghosh and the late B. C. Guha), 494
Microwave Refractometer : Measurement of Moisture Boundary Layers and Leaf Transpiration with a (David M. Gates et *al.*), 1070
Middle Jurassic Great Oolite Series, Southern England : Intertidal Zone Channel Deposits in (Dr. G deV. Klein), 1060
Mihalich, J. L., and A. R. Troiano : Delayed Failure in a Hydrogenated Face-centred Cubic Alloy of Nickel, 996
Mildew : Effect of Kinetin on Powdery (J. Dekker), 1027
Mildews and other Fungal Plant Diseases : Effect of Didecyldimethylammonium Bromide against Powdery (A. H. M. Kirby et *al.*), 514
Miledi, Dr. R. : Appointed reader in Biophysics, 1253
Miles, Dr. F. T. : Appointed Director of the Division of Reactors of the International Atomic Energy Agency, 233
Miletić, B., et *al.* : Restoration of X-irradiated *L*-cells by Means of Highly Polymerized Isologous Deoxyribonucleic Acid, 90
Milk : Caesium-137 from Fall-out in Human (A. Aarkrog), 667
  Comparison of the Caseins of Buffalo's and Cow's (R. Aschaffenburg and A. Sen, 797
Milk (Dried) Products in Relation to Phytoclimatic Zones : Caesium-137 in (W. H. Rickard et *al.*), 197
Milk Fat : Origin of Methyl Ketones found in Steam Distillates of (R. C. Lawrence and J. C. Hawke), 1276
Millar, R. H. : Oysters killed by Trematode Parasites, 616

Miller, P. M., and S. Rich : Efficiency of Infective Propagules of *Rhizoctonia solani* in reducing Vigour of Strawberry Plants, 719
Miller, R. P., and R. A. Mercer : Spontaneous Phase Changes during Rapid Cooling of Beryl Melts ; their Detection and Characterization, 683
Mills, Dr. B. Y. : Elected a Fellow of the Royal Society, 1251
Mills, G. L., and D. A. J. Armstrong : Chemical Characterization of Kinins of Human Plasma, 490
Mills, R. F. N. : Re-entrant Motion in Special Relativity, 173
Milner, H. B. : Petroleum Mulch, 241
Mineral Processing Congress : The Sixth International, 751
Minerals by Higher Plants : Assimilation of (Dr. George J. Fritz. Substance of a lecture given before the Soil and Crop Science Society, Florida), 843
Minimum Requirements for Heterotrophic Growth, and Reserve Substance in *Beggiatoa* (Ernst G. Pringsheim and Wolfgang Wiessner), 102
Ministry of Aviation : Engine Research and Development : Dr. John Remfry appointed director of, 650
  Personnel Moves, 128
  Science Officers in Industry, 20
Ministry of Education : Grants for Research, 20
  Report of the Second Commonwealth Education Conference, 752
Ministry of Power, Safety in Mines Research Establishment, 1962, Research Report No. 201, *Dust Explosions in Factories—a Review of the Literature*, 129
Ministry of Public Buildings and Works : Deputy Secretary appointed, 438
Mink : A Secondary Induced Thiamine Deficiency in (F. M. Stout et *al.*), 810
Mink initiated by a Cell-free Filtrate : Hypergammaglobulinaemia in (James B. Henson et *al.*), 206
Minorsky, Dr. Nicholas : Non-linear Oscillations, *review* by Prof. L. Goddard, 525
Miocene Period in South-Eastern Oregon : Behaviour of the Geomagnetic Field during the (N. D. Watkins), 126
Missile Guidance (Temple Press Monographs on Rockets and Missiles) (J. Clemow), *review* by G. J. Herring), 635
Mitchell, A. M. J., et *al.* : Abrupt Phase Shifts on *MSF* (60 kc/s), 580
Mitchell, Judith, and G. J. V. Nossal : Ribonucleic Acid Metabolism in the Plasma Cell Sequence, 1121
Mitchell, J. R. A., and A. J. Honour : Platelet Clumping *in vivo*, 1019
Mitchell, Dr. P., et *al.* : Culture of Strain *L* Cells in Suspension : Replacement of Polymer by Traces of Trypsin in a Defined Medium, 982
Mitcheson, Prof. J. C. : Retires as Professor of Mining, 541
Miyamoto, T. : Effect of Treatment of Seeds with 2-Chloroethanol on the Resistance to Boron Toxicity in Wheat Seedlings, 620
Model Experiments for Vortex Columns in the Atmosphere (Dr. B. R. Morton), 840
Model System for Transcellular Active Transport (D S. Parsons), 1303
Modification of the Design of the Proposed Benelux Radio Telescope (Dr. W. N. Christiansen, Dr. W. C. Erickson and Dr. J. A. Hogbom), 940
Modified Window-trap for Assessment of Fumigant Insecticides in Experimental Trap-huts (A. Smith and D. J. Webley), 1227
Moisture Boundary Layers and Leaf Transpiration with a Microwave Refractometer : Measurement of (David M. Gates et *al.*), 1070
Molecular Addition Compounds of Polycyclic Derivatives of Cinnoline (J. F. Corbett), 177
Molecular Basis of Neoplasia, a Collection of papers presented at the Fifteenth Annual Symposium on Fundamental Cancer Research, 1961, *review* by Dr. Marthe Vogt, 113
Molecular Biochemistry (Edward M. Kosower), *review* by Dr. E. F. Hartree, 324
Molecular Biology : Dr. J. B. Finean appointed reader in, 132
  Dr. M. H. F. Wilkins appointed Professor of, 132
Molecular Deficiency of Glucose-6-Phosphate Dehydrogenase in Primaquine Sensitivity (H. N. Kirkman and B. B. Crowell), 286
Molecular Structure of Tutin (B. M. Craven), 1193
Mollison, Dr. P. L. : Appointed Professor of Haematology, 1253
Molluscs and the Coral-Algae Association : Rates of Calcium Carbonate Deposition by Deep-Sea Organisms (K. K. Turekian), 277
Molomut, N., et *al.* : Quantitative Technique for Uniform Tumour Implantation by Trocar in Gel-foam, 1309
Molyneux, Dr. L. : Biological Signals and Noise, 855
Monash University : Appointments, 1252, 1253
Monkey : Intermodality Transfer of Specific Discriminations in the (W. A. Wilson, Jun., and Olivia C. Shaffer), 107
Monkeys : Hepatitis in African (W. G. C. Bearcroft), 806
Monkeys by Injections of Heterologous Glomerular Basement Membrane and Freund's Adjuvant : Glomerulonephritis induced in (Dr. R. W. Steblay), 1173
Monoamine Oxidase-inhibiting Hydrazines on Serotonin Metabolism : Variable Action of (E. Kirberger), 1211
Monocalcium Phosphate and Calcium Carbonate : Reaction between (S. Larsen et *al.*), 317
Monogenetic Flow Folds : Geometrically Complicated (E. Williams), 68
(^{131}I)-3-Monoiodotyrosine and (^{131}I)-3,5-Diiodotyrosine of Very High Specific Activity : Preparation of (W. S. Reith and W. Tampion), 180
Montagnier, L., and F. K. Sanders), Encephalomyocarditis Virus and its Ribonucleic Acid : Sedimentation Characteristics, 1178
Moon : Impacts on the Earth and (G. S. Hawkins), 781
Moore, A. W., and E. O. Jaiyebo : Soil Nitrogen Accretion under Different Covers in a Tropical Rain-Forest Environment, 317
Moore, M. H., et *al.* : Effect of Didecyldimethylammonium Bromide against Powdery Mildews and other Fungal Plant Diseases, 514
Moore, Patrick : Distribution and Origin of Lunar Craters, 273
Moorhouse, J. E., and Dr. P. T. Haskell : A Blood-borne Factor Influencing the Activity of the Central Nervous System of the Desert Locust, 56
Mordenite : Possible Structures related to (I. S. Kerr), 1194
Moreira-Jacob, M. : *In vitro* Species (or Type) Transformation among Strains of *Brucella*, 406
Morgan, E. H., and C. B. Laurell : Neuraminidase in Mammalian Brain, 921
Morgan, J. W., and Dr. J. F. Lovering : Uranium and Thorium Abundances in Possible Upper Mantel Materials, 138
Morganucodon from Yunnan : Specimen of (H. W. Rigney), 1122
Morphology of the Mammalian Lung : Diffusing Area : Comparative Quantitative (Prof. S. M. Tenney and J. E. Remmers), 54
Morris, C. J., et *al.* : A Sensitive Qualitative Test for Sulphoxides on Paper Chromatograms, 380
Morris, I. G. : Transmission of anti-*Brucella abortus* Agglutinins across the Gut in Young Mice, 813
Morris, Dr. J. Anthony, and Dr. D. Carleton Gajdusek: Encephalopathy in Mice following Inoculation of Scrapie Sheep Brain, 1084
Morris, Dr. J. G., and Prof. H. L. Kornberg : β-Hydroxyaspartate Pathway : A New Route for Biosyntheses from Glyoxylate, 456
Morris, Dr. R. F. : Awarded the first Gold Medal of the Entomological Society of Canada, 23
Morris, R. J. H., et *al.* : Turn-over and Distribution of Water in Desert Camels, Sheep, Cattle and Kangaroos, 270
Mortality, Old (Prof. Lancelot Hogben), 230
Mortimer, J. V., and P. L. Gent : Use of Modified 'Bentone-34' for the Gas Chromatographic Separation of Aromatic Hydrocarbons, 789
Morton, A. G., et *al.* : Stimulation of Sporulation in *Penicillium* by Anhydroglucose, 723
Morton, Dr. B. R. : Model Experiments for Vortex Columns in the Atmosphere, 840
Morton, J. R., and W. E. Falconer : Electron Paramagnetic Resonance Spectrum of the Acetyl Radical, 1103
Mosaic Permselective Membranes (F. de Korosy and J. Shorr), 685
Mosaic Permselective Membranes : Enhanced Salt Diffusion along the Border-line of (F. de Korosy), 685
Mosquitoes (Californian) : Axenic Culture in Two Trichomycetes from (Truman B. Clark et *al.*), 208
Moss, D N., and S. L. Rawlins : Concentration of Carbon Dioxide inside Leaves 1320
Moss, M. S. : Appointed to the Animal Health Trust, 23
Mössbauer Effect : Third International Conference on, 1156
Moth : Longevity, Palatability and Natural Selection in Five Species of New World Saturniid (Dr. A. D. Blest), 1183
Moths and Predators : Relations between (Dr. A. D. Blest), 1046
Motion of Current Systems in the Ionosphere (J. A. Lawrie and A. T. Price), 581
Motor Oils : Rheology of (H. G. Muller), 754
"Moulds for Reinforced Plastics" : Symposium on, 1253
Mountains by Radial Contraction of the Earth : Formation of (R. A. Lyttleton) 276
Mouse : Effect of Dilution of the Diet with an Indigestible Filler on Feed Intake in the (D. C. Dalton), 909

Mouse Brain caused by 2,3-Dimercaptopropanol : Increased Uptake of Mercury in (M. Berlin and S. Ullberg), 84
Mouse Chimæras : Donor and Host Contribution to Splenomegaly in Homologous, (I. M. Zeiss and M. Fox), 673
Mouse Liver : Actomyosin-like Protein in Mitochondria of the (S. A. Neifakh and T. B. Kazakova), 1106
Mouse Lymphosarcoma Cells irradiated *in vivo* : A Multicomponent X-ray Survival Curve for (W. E. Powers and L. J. Tolmach), 710
Mouse Marrow Cells : Cytological Demonstration of the Clonal Nature of Spleen Colonies Derived from Transplanted (Dr. A. J. Becker *et al.*), 452
Mouse (MuA2) : A New Allotypic Specificity in the (S. Dubiski and B. Cinader), 705
Moustafa, Essam, and Dr. M. H. Proctor : Incorporation of Amino-Acid by Root Nodules of *Galega officinalis*, 262
Mouton, D., et *al.* : Phagocytosis of *Salmonellae* by Reticulo-endothelial Cells of New-born Piglets lacking Natural Antibody, 706
Movement : A Difference between Real and Apparent Visual (Paul A. Kolers), 271
Mowbray, J. F. : Effect of Antibody Production of Injection of an α_2-Protein Fraction, 1019
Moyer, A. W., et *al.* : Tumour Induction in *C_3H* and Swiss *ICR* Mice by Tissue Culture Preparations of Polyoma Virus, 298
MSF (60 kc/s) : Abrupt Phase Shifts on (A. M. J. Mitchell et *al.*), 580
Mucopolysaccharides : Heterogeneity of Urinary Acid (W. R. Kelley et *al.*), 1204
Mucopolysaccharides in the Skin : Thermal Injuries and Formation of (G. Berencsi and St. Krompecher), 191
Mucoproteins : Sequential Enzyme Induction : A New Approach to the Structure of Complex (Dr. S. A. Barker et *al.*), 231
Mucoraceae : β-Carotene and Sexuality in the (D. Hocking), 404
Mucosa (Rat Intestinal) during Fat Absorption : Phospholipid Composition and Turnover in (M. I. Gurr et *al.*), 79
Muggleton, D. F., et *al.* Dimetridazole : Absorption, Excretion and Metabolism in Turkeys, 1024
Mulch . Petroleum (H. B. Milner), 241
Muldal, S. : Genetic Mechanisms in Human Disease : Chromosomal Aberrations, *review*, 218
Muldal, S., et *al.* : Synthesis of Deoxyribonucleic Acid on X-Chromosomes of an XXXXY Male, 251
Muller, Dr. A., et *al.* : Electron-Transport System in Photosynthesis of Green Plants Analysed by Sensitive Flash Photometry, 987
Muller, H. G. : Rheology of Motor Oils, 754
Müller, K. J., and J. B. Alexander : Devonian Conodonts in Stratigraphic Succession of Malaya, 681
Muller-Eberhard, U., and H. Cleve : Immunoelectrophoretic Studies of the β_1-Hæm-binding Globulins (Hæmopexin) in Hereditary Hæmolytic Disorders, 602
Multicomponent X-ray Survival Curve for Mouse Lymphosarcoma Cells Irradiated *in vivo* (W. E. Powers and L. J. Tolmach), 710
Multiple Allelic Control of Chlorophyll *b* Level in *Arabidopsis thaliana* (Y. Hirono and G. P. Rédei), 1324
Multiple-beam 'Transmission-like' Fizeau Fringes in the Reflexion *Interference* System (C. McD. Hargreaves), 890
Multiple Flash-gap Technique for measuring Shock Wave Velocities (U. Berg and P. A. Persson), 65
Multiple Solid Solution on Sulphides in Sphalerite (L. J. Lawrence), 171
Muntoni, S., et *al.* : Guanidine Conditioned Infectivity of Ribonucleic Acid extracted from a Strain of Guanidine-dependent Polio-1-Virus, 315
Muramic Acid : Acetyl Derivatives of (P. M. Carroll), 694
Murdoch, J. : Appointed Lecturer in the Department of Production and Industrial Administration, 132
Murine Leukæmia : Cheek Pouch of the Syrian Hamster and Immunity to Heterotransplantation of a (R. A. Adams), 1021
Murray, I. P. C., and S. K. Bisset : Effect of 3 : 5 : 3′-triiodothyroacetic Acid on the *in vitro* Oxygen Uptake of Leucocytes of Hypopituitary Patients, 1209
Murray, R. G. E., and S. W. Watson : An Organelle confined within the Cell Wall of *Nitrosocystis oceanus* (Watson), 211
Murray Meteorite : Ultra-Violet-Absorbing Compound(s) Reported Present in the (Prof. H. Oró), 756
Musca domestica L. : Effect of Synthetic 'Queen Substance' (9-oxodec-*trans*-2-enoic acid) on Ovary Development of the Housefly (J. K. Nayar), 923
Muscle Cell : Effect of Tetraethyl Ammonium Ion on the Electrical Activity of Smooth (T. Suzuki et *al.*), 908
Muscle Cell Membrane Preparations : Binding of Insulin to a (Dr. P. M. Edelman, et *al.*), 878
Muscle Dystrophy : Alterations in Skeletal Muscle after X-irradiation and their Similarity to Changes in (R. M. Dowben and L. Zuckerman), 400
Muscle Fibres in a Mechanical Field : Adenosine Triphosphatase Activity of Glycerinated (Tsuyoshi Ohnishi and Tomoko Ohnishi), 184
Muscle Spindles in the Intercostal Muscles of the Cat : Activity of Fusimotor Fibres innervating (T. A. Sears), 1013
Museum of Applied Arts and Sciences, Sydney : Annual Report, 1961, 21
Mutation and Recombination of Flagellar Antigen *i* of *Salmonella typhimurium* (T. M. Joys and B. A. D. Stocker), 413
Mycobacteria : Cellulose Acetate Membranes for detecting Peroxidase in (R. Knox and J. K. Pickerill), 209
Mycological Congress, The Third European, will be held at Glasgow University, 1054
Mycology and Plant Pathology : C. W. R. McCreary appointed lecturer in, 132
Mycoplasmataceae : Pleuropneumonia-like Organisms (PPLO) (E. Klieneberger-Nobel), *review* by Dr. Ian Macpherson, 832
Myelocyte-Metamyelocyte Transition in the Bone Marrow of the Dog (Mary A. Maloney, Charlotte L. Weber and Dr. Harvey M. Patt), 150
Myocardial Cells of Frogs and Dogs by Autoradiography combined with Electron Microscopy : Localization of Tritiated 'Digoxin' in the (Dr. John R. Smith and Dr. Harry A. Fozzard), 562
Myristicin Fraction from Oil of Nutmeg : Composition of the (A. T. Shulgin), 379
Myzus persicae in Sugar Beet Crops : Spread of Yellows Virus by (C. R. Ribbands), 624

NACHOD, F. C., and W. D. Phillips (edited by) : Determination of Organic Structures by Physical Methods, Vol. 2, *review* by Dr. W. A. Waters, 633
Nagata, T., et *al.* : Demonstration of the Production of a New Type of Remanent Magnetization : Inversed Type of Thermo-Remanent Magnetization, 444
Nagata, T., and K. Kobayashi : Thermo-chemical Remanent Magnetization of Rocks, 476
Nagel, R., and R. Etcheverry : Types of Haptoglobins in Araucanian Indians of Chile, 187
Nakakuki, K., and Y. Nishizuka : Age Changes of the Thymus in Two High-leukæmia Strains of Mice, *SL* and *AKR*, and in their F_1 Hybrids, 1217
Nakamura, Prof. M., and Carla R. Clausen : Beta-Galactosidase of *Shigella sonnei*, 570
Nakamura, Prof. M., and C. M. Ramage : Increased Survival of Ultra-violet-irradiated *Shigella sonnei* by decreasing the Surface Tension, 1028
Nakanishi, K., et *al.* : Isolation of Lampterol, an Antitumour Substance from *Lampteromyces japonicus*, 292
Nally, R., et *al.* : Urease and Citrase of Pathogenic and Saprophytic Fungi, 359
Naphthalene on the Quenching of Liquid Scintillation Solutions : Effect of (Horace E. Dobbs), 788
Narasimham, N. A., and K. Srikameswaran : A New $^4\Pi$–$X^4\Pi$ Band System of Nitrogen Sulphide, 370
Nardi, G. L., et *al.* . Enzymatic Investigations of Partially Purified Hog Kallikrein, 1300
Nash, T., and Dr. A. C. Allison : Electron Donation and Acceptance by Carcinogenic Compounds, 758
Nashold, jun., B. S., et *al.* : Effect of Posterior Pituitary Polypeptides on the Flow of Urine after Injection in Lateral Ventricle of the Brain of a Cat, 293
Nasser, R., et *al.* : Antiserum Inhibition of the Œstrous Cycle in Normal Rats, 1117
Nastuk, William L. (edited by) : Physical Techniques in Biological Research, Vol. 4, *review* by Prof. J. A. V. Butler, 5
Natalis, P. : Behaviour of *cis* and *trans* Isomers of Decaline under Electron Impact, 284
  Steric Effect in Mass Spectra of *cis-trans* Disubstituted Ethylenes, 73
Nathans, Dr. Daniel, and Dr. Amos Neidle : Structural Requirements for Puromycin Inhibition of Protein Synthesis, 1076
National Academy of Sciences—National Research Council Committee on Biological Control of Soil-borne Plant Pathogens : Symposium on "Factors Determining the Behaviour of Plant Pathogens in Soils", 131
  National Research Council (Publication 1031), 543
National Art Gallery and Dominion Museum, Wellington : Annual Report 1961/62, 1155
National Association for Mental Health : New Research Project, 955
National Botanic Gardens of South Africa, Kirstenbosch (Phillida Brooke), 644
National Bureau of Standards : *Bibliography on Direction Finding and Related Ionospheric Propagation Topics*, Technical Note, 127, 651
National Bureau of Standards Monograph 38 : *Radiation Patterns in the Lower Ionosphere and Fresnel Zones for Elevated Antennas Over a Spherical Earth*, 130
National Institute of Sciences of India : Council for 1963, 652
National Institutes of Health : *Research Highlights in Ageing*, 22
  Activities of the National Institutes of Health in the Field of Gerontology, 22
  Research Programmes in Ageing, 22
National Museum of Wales : Extensions to, 21
National Parks and Access to the Countryside Act, 1949. Thirteenth Report of the National Parks Commission, 828
National Research Council and the Medical Research Council of Canada : Report on University Support 1961–62, 339
National Research Council of Canada : Dr. B. G. Ballard appointed President of the Council, 848
  Dr. L. Marion appointed Vice-President of the Council, 848
National Research Development Corporation, Bulletin of the, 1056
  Report and Statement of Accounts for 1961/1962, 929, 959
National Science Foundation : Bulletin No. 15, *NSF 62–17 Scientific Information Activities of Federal Agencies*, 130
  Nonconventional Technical Information Systems in Current Use, 130
  Science Course Improvement Projects, 543
  Support for Research on Information Retrieval, 1053
National Union of Teachers : *Incomes Policy and the Professional Employee*, 437
National Vegetable Research Station Association : Members' Day and the Annual General Meeting, 850
NATO : Advanced Study Institute on Palæoclimates, 23
  Summer school sponsored by, on the Surface Properties of Semi-conductors, 955
Natro Carbonatite Lava from Oldoinyo l'Engai : Fresh (Dr. C. G. B. Du Bois *et al.*), 445
Natural History of Rennell Island, British Solomon Islands (edited by Torben Wolff), 130
Nature 1962 : Contributions to, 233
Nature Conservancy. Report of the Nature Conservancy for the year ended 30th September, 1962, 440
Nature of Acetylcholine-like Activity released from Brain *in vivo* (J. C. Szerb), 1016
Nature of Biochemistry (Prof. Ernest Baldwin), *review* by Dr. K. S. Dodgson, 425
Nature of Glass in New Zealand Ignimbrites (R. C. Martin and J. F. Lewis), 1166
Nature of Orientational Defects in Ice (Prof. J. D. Dunitz), 860
Nature of the Photoreactivable Ultra-violet Lesion in Deoxyribonucleic Acid (Jane K. Setlow and Richard B. Setlow), 560
Nature of Strong Radio Sources (Prof. F. Hoyle and Prof. William A. Fowler), 533
Nature of Vestured Pits in Angiosperms (A. B. Wardrop, H. D. Ingle and G. W. Davies), 202
Naughton, Prof. John H. : Possible use of Argon-39 in the Potassium-Argon Method of Age Determination, 661
Naukkarinen, I., and H. E. Carr, jun. : Isolation of a Polar Aldosterone-like Substance from the Urine and Adrenal Incubates of Patients with Arterial Hypertension, 696
Nava, G.-C., et *al.* : Bacterial Transformation : An Antigen Specific for 'Competent' Pneumococci, 903
Nayar, J. K. : Effect of Synthetic 'Queen Substance' (9-oxodec-*trans*-2-enoic acid) on Ovary Development of the Housefly, *Musca domestica* L., 923
Necrosis in Bromobenzene, Thioacetamide, Tannic Acid Poisoning, and Inhibition by Amino-acetonitrile of the Necrosis Induced by Bromobenzene : Topographic Distribution of Hepatic (L. Fiume), 394
Necrotic Yellows Virus : Lettuce (L. L. Stubbs and R. G. Grogan), 1229
Nederlandse Keramische Vereniging and the British Ceramic Society : Science of Ceramics, Vol. 1 (edited by G. H. Steward), Proceedings of a Conference, June 1961, *review* by Dr. N. F. Astbury, 932
Negatively Stained Lipoprotein Membranes : the Validity of the Image (J. B. Finean and M. G. Rumsby), 1326
Negro Family (American) : Hypohaptoglobinæmia in an (A. J. Gottlieb et *al.*), 1214
Neidle, Dr. Amos and Dr. Daniel Nathans : Structural Requirements for Puromycin Inhibition of Protein Synthesis, 1076
Neifakh, S. A., and T. B. Kazakova : Actomyosin-like Protein in Mitochondria of the Mouse Liver, 1106
Nelken, D., and Edgar Pick : Passive Agglutination Tests, 157
Nelken, D., and N. Gilboa-Garber : Passive Agglutination Tests, 158
Nelson, A., et *al.* : Genetic Effects of Strontium-90 Injected into Male Mice, 304
Nelson, Prof. E., and Prof. G. Levy : Relationship of Plasma Salicylate Concentration to Urinary Salicylate Excretion Rate, 1269

Nelson, R. F., and B. J. Finkle : Enzyme Reactions with Phenolic Compounds : Effect of o-Methyltransferase on a Natural Substrate of Fruit Polyphenol Oxidase, 902
Nematodes : 'Campaniform-type' Organs in (W. G. Inglis), 618
Nematophagous Fungi during the Decomposition of Organic Matter in the Soil : Succession of (R. C. Cooke), 205
Nematophagous Fungus *Arthrobotrys oligospora* Fresenius : A Nematotoxin produced by the (Th. H. A. Olthof and R. H. Estey), 514
Nematotoxin produced by the Nematophagous Fungus *Arthrobotrys oligospora* Fresenius (Th. H. A. Olthof and R. H. Estey), 514
Neoplasia : a Collection of papers presented at the Fifteenth Annual Symposium on Fundamental Cancer Research, 1961 : The Molecular Basis of, *review* by Dr. Marthe Vogt, 113
Neoplastic Cells : Enzymatic Dedifferentiation of (M. Thiery and R. G. J. Willighagen), 1312
Neoplastic Disease : An Uncommon Blood Group Isoantibody (Anti-M) in (S. J. Klein *et al*.), 393
Neptune : The Discovery of (Dr. Morton Grosser), *review* by Dr. R. A. Lyttleton, 734
Nervous System Activity : Periodic Nature of Spontaneous Peripheral (Dr. A. A. Alexander *et al*.), 1169
Ness, A. G., and R. E. Strange : Effect of Chilling on Bacteria in Aqueous Suspension, 819
Nesting Habits : Body Temperature of Birds in Relation to (O. P. M. Prozesky), 401
Neuraminidase in Mammalian Brain (E. H. Morgan and C. B. Laurell), 921
Neurochemical Differences between Two Strains of Mice (Dr. James W. Maas), 255
Neurological Patients after Intracutaneous Administration of Proteolipid A extracted from Human Brain : Skin Reactions in (D. Bohme *et al*.), 609
Neurology : Experimental (Prof. Paul Glees), *review* by Lord Brain, 632
Neurone Soma Actually Generate Action Potentials ? Does the (Y. Oomura and T. Maéno), 358
Neuropharmacology : Dr. E. F. Marshall appointed Research Fellow in Experimental, 132
Neurosecretion : Release of Vasopressin by Depolarization and its Dependence on Calcium : Possible Mechanism of (W. W. Douglas), 81
Neurosurgery : H. G. Clarke appointed Research Fellow in the Department of, 1156
Neutron Activation : Rapid Microdetermination of Iodium by (M. Okada and Y. Kamemoto), 279
Rapid Non-destructive Analysis for Gold in Copper–Gold Mixtures by (M. Okada and Y. Kamemoto), 278
Neutron Activation Analyses of Snake Venoms : Presence of Copper (S. Gitter, S. Amiel, G. Gilat, T. Sonnino and Y. Welwart), 383
Neutron Capture in the Samarium Isotopes and the Formation of the Elements of the Solar System (R. L. Macklin, J. H. Gibbons and T. Inada), 369
Neutron Numbers 98, 108 and 116 (L. H. Ahrens), 993
Neutron Physics : Proceedings of the Symposium held at Rensselaer Polytechnic Institute, 1961 (edited by M. L. Yeater), *review* by Dr. P. A. Egelstaff, 117
Neveu, T., *et al*. : Repression of Delayed Hypersensitivity to Conjugated Serum Albumin during Immune Paralysis induced in Guinea Pig by Heterologous Proteins, 1023
New Allotypic Specificity in the Mouse (MuA2) (S. Dubiski and B. Cinader), 705
New $^2\Pi$–$X^2\Pi$ Band System of Nitrogen Sulphide (N. A. Narasimham and K. Srikameswaran), 370
New Chromosome Number and Karyotype in *L. radiata* (S. Bose), 1229
New Mechanism for Convection in the Mantle and Continental Accretion (F. D. Stacey), 582 ; (S. K. Runcorn), 583
New Method of Directly measuring the Galactic Magnetic Field (B. G. Clark), 474
New Physics Building at Queen Mary College, University of London (Prof. G. O. Jones), 1142
'New' Variant of Hæmoglobin A_2 and its Segregation in a Family with Hæmoglobin S (Prof. H. M. Ranney, A. S. Jacobs, Dr. T. B. Bradley, Jun., and Dr. F. A. Cordova), 164
New World Saturniid Moth : Longevity, Palatability and Natural Selection in Five Species of (Dr. A. D. Blest), 1183
New Zealand. Report of the Department of Scientific and Industrial Research for the year ended March 1962, 25
New Zealand Forest Service. Forest Research Institute, Rotorua. Report for the year 1961, 31
Newman, J. F. E., *et al*. : Chromatography of Infective Ribonucleic Acid from Foot-and-mouth Disease Virus on Calcium Phosphate, 590
Newton, Dr. P. : Growth and Nutrition of a Whole Plant, 343
Niacin Content of Coffee (R. F. Smith), 1321
Nichols, Dr. David : Echinoderms, *review* by Prof. J. E. Smith, 735
Nickel : Delayed Failure in a Hydrogenated Face-centred Cubic Alloy of (J. L. Mihelich and A. R. Troiano), 996
Orientation of Benzoic Acid Adsorbed on (A. Block), 376
Nickel II : Tetrahedral Co-ordination in *Bis-N-isopropyl* Salicylaldiminato (M. R. Fox *et al*.), 1104
Nickel Oxide : Influence of Mercury Vapour on Chemisorption of Oxygen by (H. B. Charman and R. M. Dell), 284
Nicot, G., and J.-L. Parrot : Antihistaminic Action of Lysozyme, 496
Nicotinamide Adenine Dinucleotide in Carrageenin-induced Proliferation : Concentration of (M. Luscombe), 691
Nicotinamide–Adenine Dinucleotide Phosphate in Animal Tissues : Effect of Light on the Oxidation of Reduced (H. Zwarenstein and V. van der Schyff), 714
Nicotinamide Metabolite, N′-Methyl-4-Pyridone-3-Carboxamide : Photochemistry of a (D. Abelson and A. Boyle), 460
Niece, J. L., and J. T. Barrett : Non-immune Gel Precipitin Tests with an Enzyme Antigen, 1021
Niedergerke, Dr. R. : Title of reader in Biophysics conferred on, 1156
Night Sky in February, 236 ; March, 652 ; April, 1054
Nijhawan, Dr. B. R. : Elected an honorary vice-president of the Iron and Steel Institute, London, 1156
Nilsson, A., *et al*. : A Direct Terrestrial Test of the Second Postulate of Special Relativity, 1191
Ninhydrin Reaction for Quantitative Estimation of Amino Groups in Insoluble Specimens : Use of the (P. A. Kendall), 1305
Nishiyama, A., *et al*. : Effect of Tetraethyl Ammonium Ion on the Electrical Activity of Smooth Muscle Cell, 908
Nishizuka, Y., and K. Nakakuki : Age Changes of the Thymus in Two High-leukæmia Strains of Mice, *SL* and *AKR*, and in their F_1 Hybrids, 1217
Nitrate Reductase Activity in Inbred Lines and F_1 Hybrids in Maize : Levels of (Prof. R. H. Hageman *et al*), 263
Nitric Oxide on Paraffin Pyrolyses : Mechanism of the Action of (Prof. R. G. W. Norrish and Dr. G. L. Pratt), 143
Nitride Whiskers : Aluminium (P. E. Evans and T. J. Davies), 587
Nitrification by *Arthrobacter globiformis* (H. B. Gunner), 1127
Nitrobenzene Free Radical Anion in Dimethylformamide : Electrochemical Generation and Visible Spectrum of (W. Kemula and R. Sioda), 588
o-Nitrobenzoic Acid Inhibition of Microbial Growth by Amino-Acids : Reversal of (Jerry J. Kirkland and Norman N. Durham), 210
Nitrogen Metabolism in Plants (H. S. McKee), *review* by Dr. G. Bond, 326
Nitrogen Metabolism of African Cattle Fed Diets with an Adequate Energy, Low-Protein Content (R. C. Elliott and Dr. J. H. Topps), 668
Nitrogen Source in Fungal Decomposition of Wood (A. Klingström and E. Oksbjerg), 97
Nitrogen Sulphide : A New $^2\Pi$–$X^2\Pi$ Band System of (N. A. Narasimham and K. Srikameswaran), 370
Nitrosocystis oceanus (Watson) : An Organelle confined within the Cell Wall of (R. G. E. Murray and S. W. Watson), 211
Noakes, G. R : Cavendish Problems in Classical Physics, *review*, 931
Living with the Atom, *review*, 421
Nobel : The Man and His Prizes (H. Schuck, R. Sohlman, A. Osterling), G. Liljestrand, A. Westgren, M. Siegbahn, A. Schou and N. K. Stahle. (edited by the Nobel Foundation), *review* by Lord Boyd Orr, 419
Nobel Foundation (edited by) : Nobel : The Man and His Prizes, *review* by Lord Boyd Orr, 419
Noll, Dr. H., *et al*. : Ribosomal Aggregate Engaged in Protein Synthesis : Characterization of the Ergosome, 430
Nomenclature of Isolates of Virus from Trachoma and Inclusion Blennorrhea (J. H. S. Gear, F. B. Gordon, B. R. Jones and S. D. Bell, Jun.), 26
Nomenclature of Serum Proteins (P. Grabar), 692
Non-Enzymatic Browning : Role of Phosphatides in (H. S. Burton and D. J. McWeeny), 1086
Non-Enzymatic Browning Reactions : Consideration of Sugar Stability (H. S. Burton and D. J. McWeeny), 266
Non-Immune Gel Precipitin Tests with an Enzyme Antigen (J. L. Niece and J. T Barrett), 1021
Non-linear Oscillations (Dr. Nicholas Minorsky), *review* by Prof L. S. Goddard, 525
Non-specific Precipitation Patterns obtained in Double Diffusion between Serum and Extracts of Normal Organs and Tumours (C. Deckers and J. Maisin), 397
Noradrenaline across the Human Placenta : Transmission of (M. Sandler *et al*.), 598
Nordskog, A R., and L. W. Schierman : Influence of the B Blood Group–histocompatibility Locus in Chickens on a Graft-versus-Host Reaction, 511
Norethynodrel : Termination of Pregnancy in the Rat with (B. K. Davis), 308
Norkin, S , and K. Aterman : The Periodic Acid–Schiff Reaction, 1306
Normal Mitotic Activity and Karyotype of Leucocytes from Pernicious Anæmia Patients cultured in Vitamin B_{12}-deficient Medium (A. de la Chapelle and R. Grasbeck), 607
Norman, J. N., *et al*. : *In vitro* Measurements of Oxygen Consumption of Human Heart Muscle, 802
Norrish, R. G. W., and F. H. C. Edgecombe : Vinyl Polymerization photochemically initiated by Cerous Ions, 282
Norrish, Prof. R. G. W., and Dr. G. L. Pratt : Mechanism of the Action of Nitric Oxide on Paraffin Pyrolyses, 143
North Atlantic Treaty Organization : see under NATO
Northampton College of Advanced Technology : Symposium on "Communications in Industrial Relations", 341
Norton, Dr. D. A., and J. M. Ohrt : Distances of Atoms from the 'Best' Planes of Cholesteryl Iodide, 450
Noseda, V., *et al*. : Vectorcardiogram of *Anguilla anguilla* L. and *Pleurodeles waltlii* Mich, 816
Nossal, G. J. V., and Judith Mitchell : Ribonucleic Acid Metabolism in the Plasma Cell Sequence, 1121
Notions of Niche and Competition among Animals, with Special Reference to Freshwater Fish (Dr. A. H. Weatherley), 14 ; *erratum*, 1253
Nowotny, Alois : Endotoxoid Preparations, 721
Nuclear Deoxyribonucleic Acid Content in Corona Radiata of the Ovary of the Rat (D. Vandekerckhove), 190
Nuclear Emulsions : Fading of Latent Image in Japanese Fuji *ET-7A* and *ET-6B* (Lien-Sheng Chuang and Tsong-Jen Lee), 1288
Nuclear Energy . South African National Conference on, 751
Nuclear Event : Magneto-Telluric Effects Observed in Dallas, Texas, from the July 9, 1962, High-Altitude (J. J. Burch and A. W. Green, jun.), 960
Nuclear Explosion on Radio Wave Propagation : Effect of the U.S. High-altitude (P. Rohan *et al*.), 887
Nuclear Explosions : Period and Amplitude in Atmospheric Gravity Waves from (H. Wägner and U. Ericsson), 994
"Nuclear Magnetic Resonance in Molecules of Moderate and High Molecular Weight" : Course to be held at Bradford Institute of Technology, 1054
"Nuclear Power" : Anglo-Japanese Symposium, 438
Nuclear Power : Rutherford and (David A. Keys), 842
Nuclear Power for Peaceful Purposes, 1154
Nuclear Reactor . Twentieth Anniversary of the First, 22
Nuclear Reactor Fuel Elements : Metallurgy and Fabrication (edited by Albert R. Kaufman), *review* by S. F. Pugh, 425
Nuclear Research : The European Organization for (S. Weintroub), 853
Nuclear Science : Dr. J. Walker appointed to the chair of, 1156
Nuclear Science and Engineering Corporation : Dr. Bernard Kelsch appointed Senior Scientist, 341
Nuclear Size of Live and Dead Bovine Spermatozoa (F. N. Baker and G. W. Salisbury), 820
Nuclear Tests, 1961 : Increase of Strontium-90 and Cæsium-137 in Japanese Leafy Vegetables due to the Russian (R. Ichikawa and M. Eto), 509
Nuclear Weapons Policy : American Scientists and (Robert Gilpin), *review* by R. Brightman, 1035
Nuclei : Breeding of (R. F. Strickland-Constable and R. E. A. Mason), 897
Nucleic Acid : Inhibition of Virus Multiplication by Foreign (Z. Rotem *et al*.), 564
Nucleic Acid Components : Conduction in (D. D. Eley and R. B Leslie), 898
Nucleic Acid from Vaccinia Virus and Virus-infected Cells : Attempts to Isolate Infectious (Prof. H. C. Bubel and D. A. Wolff), 867
Nucleic Acids : Hæmagglutination induced by (I. Ishiyama), 912
Nucleic Acids and Other Characteristics in Biotin-deficient and Normal *Protomyces inundatus* Cultures (L. R. G. Valadon), 96
Nucleic Acids *in vitro* : Azo Dye Liver Carcinogenesis : Reaction of Hydroxymethylaminoazobenzene with (J. J. Roberts and G. P. Warwick), 87
Nucleic Acids of Lymphatic Cells against γ-Irradiation : Chemical Protection for the Incorporation of Phosphorus-32 into (I. Honjo *et al*.), 914
Nudelman, Sol., *et al*. : Fundamentals of Infrared Technology, *review* by Prof. W. C. Price, 633
Nuffield Foundation : £50,000 Grant for the establishment of a Statistical Research Unit in Sociology at the University of Keele, 652
Nuffield Foundation and the Royal Society : Commonwealth Bursaries Awards, 850
Nukazawa, A., *et al*. : Protein Nutrition and Radiation Damage in Mice, 305

Núñez, J. A.: Probable Mechanism regulating Water Economy *Rhodnius prolixus*, 312
Nutmeg: Composition of the Myristicin Fraction from Oil of (A. T. Shulgin), 379
Nutrition: Dr. G. R. Wadsworth appointed reader in, 1253
Nutrition Society (Glasgow): Symposium on "Aspects of Chemical Change during the Processing and Storage of Foods", 1054
Nutt, Dr. C. W., *et al.*: Rate of Flotation in a Hallimond Tube, 40

OAKLEY, Dr. K. P.: Awarded the Prestwich Medal, 955
Oat Varietal Populations: Aneuploids in (J. B. Hacker and R. Riley), 924
Oberbacher, M. F., and H. M. Vines: Spectrophotometric Assay of Ascorbic Acid Oxidase, 1203
Obese-Hyperglycæmic Mice: Lipase and Glycerokinase Activities in the Adipose Tissue of (Serene Lochaya *et al.*), 182
Observation of Mixing at Optical Frequencies in a *p–n* Junction (C. H. Carmichael), 273
Observations by Biochemical Analysis and Autoradiography on Labelled Deoxyribonucleic Acid in the Normal and Regenerating Liver of Mice (Dr. Finn Devik and Miss Karen Halvorsen), 148
Observations on Potassium Hexacyanotitanate (III), (E. A. Heintz), 690
Observatory: Towards a Southern Commonwealth (Dr. S. C. B. Gascoigne), 1240
Occultation of the Crab Nebula by the Solar Corona in June 1962 (S. Basu and J. Castelli), 885
Occurrence of Abnormally High Fluoride Concentrations at Depth in the Oceans (R. Greenhalgh and J. P. Riley), 371
Occurrence of Configurational Inversion during Tritiation by the Wilzbach Method (S. J. Angyal, J. L. Garnett and R. M. Hoskinson), 485
Occurrence of *Discocotyle sagittata* on Sea Trout (D. J. Slinn), 306
Occurrence of Dormant Ascospores in Soil (J. H. Warcup and K. F. Baker), 1317
Occurrence of γ-Hydroxyarginine in Plants (E. A. Bell and A. S. L. Tirimanna), 901
Occurrence of Maximum and Minimum in the Principal Magnetic Susceptibility versus Temperature Curves (B. C. Guha), 1093
Occurrence of a Warty Layer in Vascular Cells of Plants (W. Liese and M. C. Ledbetter), 201
Ocean Basins: Meteorite Impacts, Lunar Maria, Lopoliths and (R. L. C. Gallant), 38; (Robert S. Dietz), 39
Ocean Floors: Evidence from Islands on the Spreading of (Prof. J. Tuzo Wilson), 536
Oceans: Occurrence of Abnormally High Fluoride Concentrations at Depth in the (R. Greenhalgh and J. P. Riley), 371
Octopus briareus Robson: Behaviour of Young (J. B. Messenger), 1186
Octopus vulgaris: Unidirectional Response to Angular Acceleration recorded from the Middle Cristal Nerve in the Statocyst of (H. R. Maturana and S. Sperling), 815
Oddie, B. C. V.: Clouds, Rain and Rainmaking, *review*, 1137
Odgers, M., and K. Sachs: Hydrocarbons in the Gases evolved from Steel in Vacuum Extraction at 600° C, 373
Oenothera organensis: Effect of Grafting on the Incompatibility Response of (A. Kivilaan and Chong W. Chang), 1130
Œstradiol on Spinal Cord Convulsions in Developing Rats: Effect of (A. Vernadakis and P. S. Timiras), 906
Œstrogen Sulphokinase in Chick Embryonic Cartilage: Presence of (J. B. Adams), 1007
Œstrogens and Progesterone in Ovaries of the Marine Teleost *Conger conger* (C. Lupo and G. Chieffi), 596
Œstrogens labelled with Carbon-14 with Pyridine Nucleotide in the Presence of Peroxidase: Interaction of (P. H. Jellinck and Louise Irwin), 1107
Œstrous Cycle and Ovariectomy on the Phospholipid Content of the Pineal Gland in the Rat: Influence of the (J. Zweens), 1114
Œstrous Cycle in Normal Rats: Antiserum Inhibition of the (W. P. Young *et al.*), 1117
O'Flaherty, Fred, *et al.* (edited by): The Chemistry and Technology of Leather, Vol. 3, *review* by Dr. A. I. Scott, 635
Ohashi, M., *et al.*: Isolation of Lampterol, an Antitumour Substance from *Lampteromyces japonicus*, 292

Oró, Prof. J.: Synthesis of Organic Compounds by Electric Discharges, 862
  Synthesis of Organic Compounds by High-Energy Electrons, 971
  Ultra-Violet-Absorbing Compound(s) Reported Present in the Murray Meteorite, 756
Orotic Acid and Orotidine in Heterozygotes of Congenital Orotic Aciduria: Excretion of (M. Lotz *et al.*), 194
Orotidine in Heterozygotes of Congenital Orotic Aciduria: Excretion of Orotic Acid and (M. Lotz *et al.*), 194
Ortho- and *Para*-Bromination of Dimethylaniline: Differential Isotope Effects in the (P. G. Farrell and S. F. Mason), 590
Osterberg, Prof. C., *et al.*: Radioactivity in Large Marine Plankton as a Function of Surface Area, 883
Osterling, A., *et al.*: Nobel: The Man and His Prizes (edited by the Nobel Foundation), *review* by Lord Boyd Orr, 419
Ostracod *Cypridopsis vidua* (Muller): Effect of Certain Environments on the Carapace of the Freshwater (R. A. Reyment), 512
Ostrea chilensis Philippi in the Laboratory: Breeding of the Chilean Oyster (P. R. Walne), 676
Ottewill, Dr. R. H.: Appointed lecturer in Physical Chemistry, 1253
Outer Space: Exploration of (Sir Bernard Lovell), *review* by J. R. Shakeshaft, 117
Ovariectomy on the Phospholipid Content of the Pineal Gland in the Rat: Influence of the Œstrous Cycle and (J. Zweens), 1114
Ovaries of the Marine Teleost *Conger conger*: Œstrogens and Progesterone in (C. Lupo and G. Chieffi), 596
Ovary Development of the Housefly, *Musca domestica* L.: Effect of Synthetic 'Queen Substance' (9-oxodec-*trans*-2-enoic acid) on (J. K. Nayar), 923
Ovary of the Rat: Nuclear Deoxyribonucleic Acid Content in Corona Radiata of the (D. Vandekerckhove), 190
Overseas Technical Co-operation, 750
Oxender, Dale L., and Halvor N. Christensen: Evidence for Two Types of Mediation of Neutral Amino-Acid Transport in Ehrlich Cells, 765
Oxidation of β-Carotene: Formation of Vitamin A Acid (R. K. Barua and A. B. Barua), 594
Oxidation of Plutonium in Moist Air and Argon (J. B. Raynor and J. F. Sackman), 587
Oxidation of Reduced Nicotinamide–Adenine Dinucleotide Phosphate in Animal Tissues: Effect of Light on the (H. Zwarenstein and V. van der Schyff), 714
Oxidations and Transhydrogenations Involving Pyridine–Dinucleotides Catalysed by Bovine Milk Xanthine Oxidase (Dr. D. A. Gilbert), 1066
Oxidized Lipid Diet on the Fatty Acid Composition of Blood and Tissues: Influence of Pregnancy and an (H. Kaunitz *et al.*), 600
Oxley, Dr. P. L. B.: Appointed Lecturer in the Department of Production and Industrial Administration, 132
Oxnard, C. E., *et al.*: Vitamin B_{12} in the Serum of the Rhesus Monkey, 186

9-oxodec-*trans*-2-enoic acid on Ovary Development of the Housefly, *Musca domestica* L. : Effect of Synthetic 'Queen Substance' (J. K. Nayar), 923
Oxygen Atoms in UO$_{2+x}$: Positions of the (B. T. M. Willis), 755
Oxygen by Nickel Oxide : Influence of Mercury Vapour on Chemisorption of (H. B. Charman and R. M. Dell), 284
Oxygen-18 by Activation Analysis : Quantitative Determination of (D. E. Solberg, *et al.*), 611
Oxygen-18/Oxygen-16 Ratio in Surface Snow and Ice from Queen Maud Land, Antarctica : Geographical Variations of (R. Gonfiantini *et al.*), 1096
Oxygen Consumption of Human Heart Muscle · *In vitro* Measurements of (J. N. Norman *et al.*), 802
Oxygen on Fungi : Effects of High Partial Pressures of (Prof. John Caldwell), 772
Oxygen Uptake of Leucocytes of Hypopituitary Patients : Effect of 3 : 5 : 3'-tri-iodothyroacetic Acid on the *in vitro* (I. P. C. Murray and S. K. Bisset), 1209
Oyster (*Ostrea chilensis* Philippi) in the Laboratory : Breeding of the Chilean (P. R. Walne), 676
Oysters : Abbreviated Pelagic Life of Chilean and New Zealand (R. H. Millar and P. J. Hollis), 512
Oysters killed by Trematode Parasites (R. H. Millar), 616
Ozato, K., and T. S. Okada : Enzymatic Activities of the Soluble Antigens in Kidney Microsomes, 1310
Ozima, M., *et al.* : Demonstration of the Production of a New Type of Remanent Magnetization : Inversed Type of Thermo-Remanent Magnetization, 444
Ozonophilic Basidiomycete : *Armillaria mellea* : an (Martha D. Berliner), 309

PAAL, G., *et al* : Skin Reactions in Neurological Patients after Intracutaneous Administration of Proteolipid A extracted from Human Brain, 609
Padnos, M., *et al.* : Quantitative Technique for Uniform Tumour Implantation by Trocar in Gel-foam, 1309
Paediatrics : Dr. L. B. Strang appointed reader in, 132
Paerels, G. B., and H. W. Geluk : Synthesis of some 3-Deoxy-heptulosonic Acids (3-Deoxy-2-keto-heptonic Acids), 379
Paired Helical Filaments in Electron Microscopy of Alzheimer's Disease (M. Kidd), 192
Palaeoclimates : Advanced Study Institute on (under the auspices of NATO), 23
Palaeomagnetic Evidence of Fossil Axes of Rotation of the Earth : Geomagnetic and (Dr. K. M. Creer), 122
Palaeomagnetic Studies in the U.S.S.R. (Prof. S. I. Tomkeieff), 546
Palaeontology in the U.S.S.R. (Prof. S. I. Tomkeieff), 854
Palladium and Palladium Alloys : Electrical Storage and Hydrogen Transfer between Electrodes of (J. C. Barton *et al.*), 1293
Palms and Chromosomes . Finger-Prints, (Prof. L. S. Penrose), 933
Pancreas by D-Mannoheptulose : Block of Insulin Secretion from the (Dr. H. G. Coore *et al.*), 1264
Pangborn, R. M., *et al.* : Influence of Hunger on Olfactory Acuity, 108
Paoletti, I., *et al.* : Characters of Mammary Tumours in *BALB/c* Female Mice Foster-nursed by *C3H* and *RIII* Mothers, 505
Papain into Rabbits : Glycoprotein Excretion following the Injection of (A. J. Anderson *et al.*), 707
Paper : Formation and Structure of, Transactions of the Symposium held at Oxford, 1961. (edited by Francis Bolam), Vols. I and 2, *review* by Dr. F. Lyth Hudson, 116
Paper Chromatograms : Sensitive Qualitative Test for Sulphoxides on (F. J. Thompson *et al.*), 380
Paper Chromatograms for Iodine (^{127}I → ^{128}I) ; Activation Analysis of (A. Dimitriadou *et al.*), 446
Paper Chromatography : A Mathematical Basis for the Solvent-Reversal Technique of (B. Weiss *et al.*), 280
Paper Chromatography of Organic Acids (H. A. W. Blundstone), 377
Paper Electrochromatography of Clay Minerals (B. L. McNeal and J. L. Young), 1132
Para-Bromination of Dimethylaniline : Differential Isotope Effects in the *Ortho*- and (P. G. Farrel and S. F. Mason), 590
Paraffin Pyrolyses : Mechanism of the Action of Nitric Oxide on (Prof. R. G. W. Norrish and Dr. G. L. Pratt), 143
Paragonite from the Dalradian (M. J. McNamara), 1193
para-Influenza : Intranuclear Inclusions produced by Bovine (A. E. Churchill), 409
Paramecium aurelia : Chemical and Immunological Comparisons of Allelic Immobilization Antigens in (I. G. Jones and G. H. Beale), 205
Paramecium aurelia, Stock 51 : Deoxyribonucleic Acid Base Composition of Kappa and (J. Smith-Sonneborn *et al.*), 385
Paramecium aurelia to Cigarette Components : Differential Responses of (Prof. Harry Wang), 946
Paraquat as a Substitute for Ploughing : Destruction of Pastures by (A. E. M. Hood *et al.*), 748
Parasite : Antigenic Relationship between Host and (Dr. J. K. Dineen), 471
Parasitism : Immunological Aspects of (Dr. J. K. Dineen), 268
Parasitology : Tropical (Prof. J. F. A. Sprent), 1256
Parathyroid Growth and Secretion *in vitro* : Regulation by Calcium of (L. G. Raisz), 1115
Parathyroid Hormone in Tissue Culture : Stimulation of Bone Resorption by (L. G. Raisz), 1015
Pardoe, Mrs. Grace I., *et al.* : Sequential Enzyme Induction : A New Approach to the Structure of Complex Mucoproteins, 231
Paris, P., *et al.* : Change of Phytol into Chlorophyll *a* in *Chlorella vulgaris*, 1219

Pflanzen : Chemotaxonomie der (Prof. R. Hegnauer), Band I, *review* by Dr. L Wislicki, 627

Pfleger, K., *et al.* : Beginning of the Accumulation of Vanadium during the Early Development of the Ascidian *Phallusia namillata* Cuvier, 1223

Phage-neutralizing Antibodies produced by New-born Rabbits : Properties of (B. Pernis *et al.*), 807

Phagocytosis of *Salmonellae* by Reticulo-endothelial Cells of New-born Piglets lacking Natural Antibody (D. Mouton, Y. Bouthillier, G. Biozzi and C. Stiffel), 706

Phallusia namillata Cuvier : Beginning of the Accumulation of Vanadium during the Early Development of the Ascidian (H. J. Bielig *et al.*), 1223

Phänomenologische Psychologie : Vorlesungen Sommersemester 1925 (Von Edmund Husserl. Herausgegeben von Walter Biemel.) Husserliana, Band 9, *review* by F. I. G. Rawlins, 419

Pharmacology : Dr. J. R. Hodges appointed reader in, 1253

Phase Shifts in the Human Retina (F. Veringa), 998

Phatak, T. C., and A. K. Chatterji : Reaction of Lime with Ferric Oxide, 350

  Semiconductivity and Cementing Action in Hydraulic-bond Type Cements, 656

Phenolic Compounds : Effect of *O*-Methyltransferase on a Natural Substrate of Fruit Polyphenol Oxidase : Enzyme Reactions with (B. J. Finkle and R. F. Nelson), 902

Phenomena occurring at Electrically Stressed Metallic Surfaces in Long Gaps in Vacuum (R. Hawley, B Loy and R. L. Craik), 274

Phenyl Isocyanate with 2,3-Epoxy Propyl Phenyl Ether (Phenyl Glycidyl Ether) : Reaction of (D. A. Smith), 285

Phenylalanine–Tyrosine-supplemented Diets : Urinary Amino-Acids on (M. J. Carver and R. Paska) 493

Philipson, W. R., and D. E. G. Sheat : Induction of Callus on Decapitated Hypocotyls of *Helianthus* by *Escherichia coli* and other Bacteria, 204

Phillips, Dr. C. G. : Elected a Fellow of the Royal Society, 1251

Phillips, M. J., *et al.* : Selective Poisoning of Catalytic Activity, 487

Phillips, W. D., and F. C Nachod (edited by) : Determination of Organic Structures by Physical Methods, Vol. 2, *review* by Dr W. A. Waters, 633

Philpot, J. St. L., and J. H Barnes : Polycarboxylic and Phosphonitrilic Acids as Radioprotectors : Effectiveness of Pyromellitic Acid, 248

Phosphate : Increase of Plant Virus Infection by Magnesium in the Presence of (C I. Kado), 925

Phosphate-mediated Cross-linkages in Hard Tissue Collagens : Presence of (A. Veis and R. J. Schlueter), 1204

Phosphatides in Non-Enzymatic Browning : Role of (H S. Burton and D. J. McWeeny), 1086

Phosphatido-peptide Fraction in Liver Cell Membrane and its Possible Role in the Active Transport of Amino-acids . Presence of a (E. Tria and O. Barnabei), 598

Phospholipid Composition and Turnover in Rat Intestinal Mucosa during Fat Absorption (M. I. Gurr, W. F. R. Pover, J. N. Hawthorne and A. C. Frazer), 79

Phospholipid Content of the Pineal Gland in the Rat : Influence of the Œstrous Cycle and Ovariectomy on the (J. Zweens), 1114

Phosphonitrilic Acids as Radioprotectors : Effectiveness of Pyromellitic Acid : Polycarboxylic and (J. H. Barnes and J. St. L. Philpot), 248

Phosphorescence in Plastics (C. F. Forster and E. F. Rickard), 1199

Phosphorescence Radiation in Aromatic Hydrocarbons . Origin of the (M. A. El-Sayed), 481

Phosphorus-32 in Radiosensitive Organs after Whole-body Irradiation in Rats : Decreased Incorporation of (Z. Dienstbier and F. Vitek), 198

Phosphorus-32 into Nucleic Acids of Lymphatic Cells against γ-Irradiation : Chemical Protection for the Incorporation of (I Honjo *et a.*), 914

Phosphorylase Enzymes in Cardiac Contraction : A Proposed Theory for the Rhythmical Production of Energy in the Heart . Role of the (Niels Haugaard), 1072

Photobiology Group : Election of Officers, 132

Photochemistry of a Nicotinamide Metabolite, N′-Methyl-4-Pyridone-3-Carboxamide (D. Abelson and A. Boyle), 460

Photochemistry of Thymine (M. Daniels and A. Grimison), 484

Photoconductivity of Manganous Phthalocyanine (P. Day, G. Scregg and R. J. P. Williams), 589

Photokinetic Function of Aphid Antennæ (C. O. Booth), 265

Photometric Observations from the Southern Hemisphere of 5577A Emission from the Aurora on October 28, 1961 (C. T. Lewis), 992

Photometry : Electron-Transport System in Photosynthesis of Green Plants Analysed by Sensitive Flash (Prof. H. T. Witt *et al.*), 987

Phthalocyanine : Photoconductivity of Manganous (P. Day *et al.*), 589

Physical and Chemical Properties of Two New Small Bacteriophages (D. A. Marvin and H. Hoffmann-Berling), 517

Physical Chemistry : Annual Review of, Vol 13 (edited by H. Eyring), *review* by Prof. J. R. Partington, 632

  Dr. R. H. Ottewill appointed lecturer in, 1253

Physical Chemistry of Process Metallurgy : An International Symposium, Pittsburgh, 1959 (edited by George R. St. Pierre), Parts I and 2 (Metallurgical Society Conferences, Vols. 7 and 8), *review* by Prof. F. C. Thompson, 1036

"Physical Processes in Radiation Biology" Symposium to be held on, 543

Physical Techniques in Biological Research. (edited by William L. Nastuk). Vol 4, *review* by Prof. J. A V. Butler, 5

Physics : Cavendish Problems in Classical (edited by Prof. A. B. Pippard. Compiled by the Staff of the Cavendish Laboratory), *review* by G. R. Noakes, 931

  Connexion between Local and Global (M. C. Goodall), 994

  Dr. B. R. Coles appointed to a readership in, 1156

  Dr. S. J. Wyard appointed to a readership in, 1156

Physics for the Modern World (Prof. E. N. da C. Andrade) (Science for the Modern World Series, Vol. 2), *review*, 422

Physiology : J. A. McCracken appointed Research Fellow in, 132

  Dr. Anita Mandl appointed reader in Reproductive, 132

  Dr. Patricia P. Scott appointed reader in, 1253

  Dr. Bertha Singer appointed Lecturer in, 132

Physiology and Biochemistry : Advances in Comparative (edited by O. Lowenstein), Vol. I, review by Prof. D. C. Harrison, 526

Physiology and Psychology in Arid Conditions : Environmental (Dr. C. S. Leithead), 1057

Phytoclimatic Zones : Cæsium-137 in Dried Milk Products in Relation to (W. H. Rickard *et al.*), 197

Phytol into Chlorophyll *a* in *Chlorella vulgaris* : Change of (L. Branco *et al.*), 1219

Phytotoxin in Red-ring Infected Trees : Possible Presence of a (L. C. Goberdhan), 619

Piazza, M., and F. Tancredi : Tryptophan–Nicotinic Acid Metabolism in Subjects recently or long since recovered from Viral Hepatitis, 903

Picciotto, E., *et al.* : Geographical Variations of Oxygen-18/Oxygen-16 Ratio in Surface Snow and Ice from Queen Maud Land, Antarctica, 1096

Pick, Edgar, and D. Nelken : Passive Agglutination Tests, 157

Pickerill, J. K., and R. Knox : Cellulose Acetate Membranes for detecting Peroxidase in Mycobacteria, 209

Picou, D., and J. C. Waterlow : Estimation of Small Amounts of Sulphate by Precipitation with Radioactive Barium, 1103

Piezoelectric Effect in Bone (M. H. Shamos, L. S. Lavine and M. I. Shamos), 81

Pig Serum Proteins : Starch-gel Electrophoresis of (R. K. Scopes), 1201

Pigeons : Effects of Lysergic Acid Diethylamide on the Nesting Behaviour of Male (E. Rosen and A. Iovino), 614

Piglets Lacking Natural Antibody : Phagocytosis of *Salmonellae* by Reticulo-endothelial Cells of New-born (D. Mouton *et al.*), 706

Pigman, W , *et al.* : Permeability of Dermal Connective Tissue in Normal and Scorbutic Guinea Pigs, 906

Pigments : Pre-Lumirhodopsin and the Bleaching of Visual (T. Yoshizawa and G. Wald), 1279

Pigmy Tools from the Andaman Islands (P. C. Dutta), 624

Pigs : Effect of Dietary Calcium Lactate and Lactate Acid on Fæcal *Escherichia coli* counts in (G. S. Burnett and J. Hanna), 815

Pigs as Hosts of *Glossina vanhoofi* Henrard and *Trypanosoma suis* Ochmann in the Central African Forest : Wild (L. van den Berghe and A. J. Zaghi), 1126

Pilkington, T. R. E., and J. G. Bearn : Effect of Total Thyroidectomy in the Rabbit Foetus on Foetal Cholesterol Metabolism, 1302

Pincus, Gregory (edited by) : Recent Progress in Hormone Research. Vol. 17 : Proceedings of the 1960 Laurentian Hormone Conference, *review* by Dr. G. S. Boyd, 115

Pineal Gland in the Rat : Influence of the Œstrous Cycle and Ovariectomy on the Phospholipid Content of the (J. Zweens), 1114

Pinkerton, J. H. M , *et al.* : Transmission of Noradrenaline across the Human Placenta 598

Pinus radiata : Carbohydrate Metabolism in the Sapwood of (A. T. Wilson and J. M. Gumbley), 711

Pippard, Prof. A. B. (edited by). (Compiled by the Staff of the Cavendish Laboratory). Cavendish Problems in Classical Physics, *review* by G. R Noakes, 931

Pirie, N. W. : Viruses, Genes and Cistrons, 568

Pirofsky, B., and M Cordova Bivalent Nature of Incomplete Anti-D(Rho), 392

Placenta Transmission of Noradrenaline across the Human (M. Sandler *et al.*), 598

Placental Tissue : Growth of Transplantable Cancer in Rats previously injected with (R. M. Wynn *et al*), 606

Plain, G. J., and Karen E. Plain : Decay and Recovery of Luminescent Ability in *Gonyaulax monilata*, 1124

Plain, Karen E , and G J. Plain : Decay and Recovery of Luminescent Ability in *Gonyaulax monilata*, 1124

Planas, José . Serum Iron in Normal and Castrated Mammals, 186

Planning, 28, 19 November, 1962, 234

Plant : Growth and Nutrition of a Whole (Dr. P. Newton), 343

Plant Amines : Spectrophotometric Micro-Estimation of some Simple (M. Richardson), 290

Plant Cells from Shake Cultures during Growth and Division : An Optically Efficient Method for observing Single (Ernest Ball), 103

Plant Diseases : Effect of Didecyldimethylammonium Bromide against Powdery Mildews and other Fungal (A. H. M Kirby *et al.*), 514

Plant Life of Palestine : Israel and Jordan (Prof. Michael Zohary), *review* by R. D. Meikle, 528

Plant Pathogens : Symposium "Factors Determining the Behaviour of Plant Pathogens in Soil", 131

Plant Phenolics Group organizing a symposium to be held in April 1963, 543

Plant Species : Chromosome Numbers of Central and Northwest European (Askell Love and Doris Love) (Opera Botanica" a Societate Botanica Lundensi, Vol. 5), *review* by Dr. V. H Heywood, 114

"Plant Tissue Culture" : International Conference on, 1156

Plant Virus Infection by Magnesium in the Presence of Phosphate : Increase of (C. I. Kado), 925

Plants : Assimilation of Minerals by Higher (Dr. George J. Fritz. Substance of a lecture given before the Soil and Crop Science Society, Florida), 843

  Electron-Transport System in Photosynthesis of Green Plants Analysed by Sensitive Flash Photometry (Prof. H. T. Witt *et al.*), 987

  Nitrogen Metabolism in (H. S. McKee), *review* by Dr. G. Bond 326

  Occurrence of γ-Hydroxyarginine in (E. A. Bell and A. S. L. Tirimanna), 901

  Occurrence of a Warty Layer in Vascular Cells of (W. Liese and M. C. Ledbetter), 201

  Rapid Changes in Transpiration in (Dr. Henry Rufelt), 985

Plaque Counting of Vaccinia Virus : Statistical Variation Found at Pock and (Dr. K. Mal and Dr. K. Bonitz), 166

Plasma : Chemical Characterization of Kinins of Human (D. A. J. Armstrong and G L. Mills), 490

  In vitro Abnormality of the Blood in Von Willebrand's Disease correctable by Normal (M. B. Zucker), 601

  Separation of Polypeptides bound by Albumin in Human (A. L. Rubin *et al.*), 1009

Plasma Antihæmophilic Factor : Synthesis of (W. D. McLester and J. B. Graham), 708

Plasma Cell Sequence : Ribonucleic Acid Metabolism in the (Judith Mitchell and G. J. V. Nossal), 1121

Plasma in Hæmorrhagic Disorders (Von Willebrand and Glanzmann Disease) : Ratio Adenosine Triphosphate/Adenosine Diphosphate in Platelet-rich (J. P. Caen), 504

Plasma Proteins of C_3H Strain Mice, found by Cellulose-Acetate and Starch-Gel Electrophoresis : A Comparison of the (E. J. Duke), 288

Plasma Salicylate Concentration to Urinary Salicylate Excretion Rate : Relationship of (Prof. E. Nelson and Prof. G. Levy), 1269

Plasma Triglycerides and Thrombosis in Rats (L. Bizzi, A. N. Howard and G. A. Gresham), 195

Plasminogen-induced Capillary Permeability : Antagonistic Action of Urokinase to Bradykinin- and (A. L. Copley and V. Tusuluca), 294

Plastics : Phosphorescence in (C. F. Forster and E. F Rickard), 1199

Plastics Institute Reinforced Plastics Group : Symposium on "Moulds for Reinforced Plastics", 1253

Platelet Clumping *in vivo* (A. J. Honour and J. R. A. Mitchell), 1019

Platinum and Boron under Pressure . Reaction of (E. D. Whitney and R. F. Giese, Jun), 1293

Pleurodeles waltlii Mich. : Vectorcardiogram of *Anguilla anguilla* L. and (V. Noseda, *et al.*), 816

Pleuroperitoneal Fluid Proteins and Antibody from Guinea Pigs : Electrophoretic Analysis of Serum and (J. Banovitz et *al*.), 704
Pleuropneumonia-like Organisms (PPLO) Mycoplasmataceae (E. Klieneberger-Nobel), *review* by Dr. Ian Macpherson, 832
Ploughing : Destruction of Pastures by Paraquat as a Substitute for (A. E. M. Hood et *al*.), 748
Plummer, G. : Poliovirus Neutralizing Properties of Equine and Other Sera 870
Plutonium in Moist Air and Argon : Oxidation of (J. B. Raynor and J. F. Sackman), 587
Pneumococci : Bacterial Transformation : an Antigen Specific for 'Competent', (G.-C. Nava et *al*.), 903
Pock and Plaque Counting of Vaccinia Virus : Statistical Variation Found at (Dr. K. Mai and Dr. K. Bonitz), 166
Pogonophora from British Coastal Waters (A. D. McIntyre), 616
Poinsettia by Gibberellic Acid : Inhibition of Flowering in (C. G. Guttridge), 920
Poisoning of Catalytic Activity : Selective (M. J. Phillips et *al*.), 487
Polani, Prof. P. E., et *al*. : Evidence that the Xg Blood Group Genes are on the Short Arm of the X Chromosome, 648
Polar Aldosterone-like Substance from the Urine and Adrenal Incubates of Patients with Arterial Hypertension : Isolation of a (H. E. Carr, jun., and I. Naukkarinen), 696
Polarizability Theories of Polynucleotide Hypochromism (H. DeVoe), 1295; (J. J. Weiss), 1296
Polarization and Classification of Radio Sources (Dr. R. D. Davies and G. L. Verschuur), 32
Polarization Measurements · Determination of Relative Ages of Lunar Craters by Albedo and (G. Fielder), 69
Polarization of Radio Sources and Faraday Rotation Effects in the Galaxy (F. F. Gardner and J. B. Whiteoak), 1162
Polarographic Behaviour of the Hexa-amminechromium(III) Ion : Role of Hydrogen Ions (N. Tanaka and G. Satô), 176
Polarographic Determination of Fural (J. Davídek), 378
Polarographic Measurements of Electron Donation and Acceptance by Carcinogenic Compounds (Dr. A. C. Allison, Dr. M. E. Peover and T. A. Gough), 764
Polgase, W. J. . Immunization against Ehrlich's Ascites Carcinoma with Streptomycin Complexes from Tumour Cells, 301
Poliomyelitis Viruses : Effect of Puromycin on the Replication of Western Equine Encephalitis and (Dr. E. Wecker), 1277
Polio-I-Virus : Guanidine Conditioned Infectivity of Ribonucleic Acid extracted from a Strain of Guanidine-dependent (B. Loddo et *al*.), 315
Poliovirus Neutralizing Properties of Equine and Other Sera (G. Plummer), 870
Polycarboxylic and Phosphonitrilic Acids as Radioprotectors : Effectiveness of Pyromellitic Acid (J. H. Barnes and J. St. L. Philpot), 248
Polychaetes : Accumulation of Haematins by (R. P. Dales), 1302
Polycyclic Derivatives of Cinnoline : Molecular Addition Compounds of (J. F. Corbett), 177
Polycyclic Hydrocarbons and their Derivatives : Excimer Formation in (Dr. J. B. Birks and L. G. Christophorou), 1064
Poly-β-hydroxybutyric Acid : Identification of Early Labelled Products of CO_2-Fixation by Hydrogen Bacteria accumulating (P. Hirsch et *al*.), 313
Polyamines Mutagenic for Bacteriophage *T4B* (J. W. Drake), 1028
Polymer by Traces of Trypsin in a Defined Medium : Culture of Strain *L* Cells in Suspension : Replacement of (Dr. R. Sinclair et *al*.), 982
Polymer Solutions at Low Shear Gradients : Rheopexy in Dilute (A. Peterlin and D. T. Turner), 488
Polymorphism in *Dactylis glomerata* Sub-species *woronowii* : Balanced (P. L. Curran), 105
Polynucleotide Hypochromism : Polarizability Theories of (H. DeVoe), 1295 ; (J. J. Weiss), 1296
Polyoma Virus : Tumour Induction in *C_3H* and Swiss *ICR* Mice by Tissue Culture Preparations of (R. Wallace et *al*.), 298
Polypeptides : Role of Optical Isomers in Determining the Antigenicity of Synthetic (Thomas J. Gill, III, et *al*.), 746
Polypeptides bound by Albumin in Human Plasma : Separation of (A. L. Rubin et *al*.), 1009
Polypeptides with known Amino-acid Sequence · Antigenicity of Synthetic (Prof. A. E. Axelrod et *al*.), 146
Polyphagous Insect, *Schistocerca gregaria* Feeding Stimulants required by a (D. Goodhue), 405
Polyploidization : A Presumed Obstacle to Mammalian (Yngve Melander), 152
Polythene : Intrinsic Electric Strength of (Dr. R. Cooper et *al*.), 663
Polyvinylpyrrolidone in Preservation of Bone Marrow : Optimal Conditions and Comparative Effectiveness of Dimethyl Sulphoxide and (M. Persidsky and V. Richards), 1010
Poncet, Inna B., et *al*. : Heterogeneity of Urinary Acid Mucopolysaccharides, 1204
Ponder, Eric, and Ruth V. Ponder · Effect of Oleic Acid on the Mobility of Human Red Cells, and its Effect on Human Serum Protein Fractions, 178
Ponder, Ruth V., and Eric Ponder : Effect of Oleic Acid on the Mobility of Human Red Cells, and its Effect on Human Serum Protein Fractions, 178
Pondman, K. W., et *al*. : Qualitative Differences in the Mechanism of Complement Fixation, 911
Ponz, P., and J. M. Llinás · Essential —SH Groups in Liver Ketohexokinase, 696
Population Densities (II) : Bacterial Growth at Low (H. W. Jannasch), 1322
Population II Stars : Deficiency of Metals in (S. Bashkin), 1091
Populations : Determination of Haptoglobin-groups Frequencies by Starch-gel and Agar-gel Electrophoresis Application to Belgian and Burundi (M. van Sande et *al*.), 603
Porath Zone Electrophoresis and Starch-gel Electrophoresis : Combination Analysis of Rabbit Serum Proteins, using High-resolution (W. A. Hemmings and R. E. Jones), 695
Porcile, E., et *al*. : Solvent-induced Changes in the Absorbancy of Isolated Chloroplast Fragments, 1110
Porcine Muscle : Electron Microscopy of Post-mortem Changes in (R. G. Cassens et *al*.), 1119
Porter, Prof. George · Chemistry, Physics and Biology for the Modern World, Chemistry (Science for the Modern World Series, Vol. I), *review*, 422
Positions of the Oxygen Atoms in $UO_{2.13}$ (B. T. M. Willis), 755
Possible Application of the Mass-Energy Cycle on a Micro- and Macro-Scopic Scale in the Universe (J. L. Hughes), 441
Possible Mechanism of Action of Calcium and some Psychotomimetic Agents on Membranes (L. G. Abood, I. Koyama and H. Kimizuka), 367
Possible Mechanism of Neurosecretion : Release of Vasopressin by Depolarization and its Dependence on Calcium (W. W. Douglas), 81
Possible Presence of a Phytotoxin in Red-ring Infected Trees (L. C. Goberdhan), 619
Possible Radiation Damage Effects in Barium Chromate Crystals (T. Adamski and L. Trojanowski), 1005
Possible Relationship between Photosynthesis and the Rise in Respiration in Diseased Leaves (K. J. Scott and R. M. Smillie), 1319
Possible Role for Minor Bases in Ribonucleic Acid (R. E. F. Matthews), 796
Possible Role of Meteorites in the Origin of Life (J. J. Gilvarry and A. R. Hochstim), 624
Possible Structures related to Mordenite (I. S. Kerr), 1194
Possible Use of Argon-39 in the Potassium-Argon Method of Age Determination (Prof. John J. Naughton), 661
Post Office Engineering Research Station, 128
Post-mortem Changes in Porcine Muscle : Electron Microscopy of (R. G. Cassens et *al*.), 1119
Post-mortem Lability of Skeletal Muscle Proteins (R. K. Scopes and R. A. Lawrie), 1202
Posterior Pituitary Polypeptides on the Flow of Urine after Injection in Lateral Ventricle of the Brain of a Cat : Effect of (B. S. Nashold, Jun., et *al*), 293
Potassium/Argon Age Determination from a Lewisian Inlier (J. A. Miller, A. J. Barber and N. H. Kempton), 1095
Potassium-Argon Ages from Western Oahu, Hawaii (Ian McDougall), 344
Potassium-Argon Method of Age Determination : Possible use of Argon-39 in the (Prof. John J. Naughton), 661
Potassium Hexacyanotitanate (III) : Observations on (E. A. Heintz), 690
Potassium Ions : Possible Relationship to Magnetism : Effect of Hydrogen Ion on the Rates of Migration of Sodium and (William K George) ; (Simo Salminen), 1209
Potassium Ions in the Rat's Intestine : Transport of (A. Gilman et *al*.), 1210
Potato Crop : Optimum Leaf Area Index in the (P. Harper), 917
Potatoes : Correlated Seed and Tuber Dormancy in (N. W. Simmonds), 720
Potentiating Effect of 5-Fluorouracil on the *in vitro* Antipoliovirus Activity of Guanidine (B. Loddo, W. Ferrari, A. Spanedda and G. Brotzu) 408
Poulik, E., et *al*. : Serum Transferrins in Chimpanzees, 259
Povejsil, Donald J., et *al*. : Airborne Radar (Principles of Guided Missile Design), *review* by R. Aspinall, 220
Pover, W. F. R., et *al*. : Phospholipid Composition and Turnover in Rat Intestinal Mucosa during Fat Absorption, 79
Powers, W. E., and L. J. Tolmach : A Multicomponent X-ray Survival Curve for Mouse Lymphosarcoma Cells Irradiated *in vivo*, 710
Poynter, F. N. L., et *al*. : An annotated translation of "Prelectiones Anatomiae Universalis" (Lectures on the Whole of Anatomy, by William Harvey), *review* by Sir Russell Brock, 523
Prange, jun., A. J., et *al*. : Diminution of Imipramine Mortality in Hypothyroid Mice, 1212
Pratt, Dr. G. L., and Prof. R. G. W. Norrish : Mechanism of the Action of Nitric Oxide on Paraffin Pyrolyses, 143
Preble, Edward, and Abram Kardiner : They Studied Man, *review* by Prof. R. Firth, 419
Precambrian Atmosphere (C. F. Davidson), 893 ; (M. G. Rutten), 894
Precambrian Volcanic Complex : Large Ring Structures in a South Australian (A. R. Crawford), 140
Precorticotrophin in Blood : Distribution of (P. R. Dasgupta), 388
Precursors of Carcinogenic Hydrocarbons in Tobacco Smoke (Dr. E. Gil-Av and Dr. J. Shabtai), 1065
Predators : Relations between Moths and (Dr. A. D. Blest), 1046
Prediction of Spontaneous Hereditary Diabetes Mellitus in Chinese Hamsters by Means of Elevated Alpha-2 Serum-levels (M. N. Green, G. Yerganian and H. J. Gagnon), 396
Prednisolone by 2-Methyl-1,4-naphthoquinone : Enhancement of the Effect of (Gy. Fekete et *al*.), 291
Pregnancy and an Oxidized Lipid Diet on the Fatty Acid Composition of Blood and Tissues : Influence of (H. Kaunitz et *al*.), 600
Pregnancy in the Rat with Norethynodrel : Termination of (B. K. Davis), 308
Pregnant Sheep by a Continuous Infusion Isotope Dilution Method : Glucose Utilization in (E. J. H. Ford), 614
Prehistory : The Idea of (Dr. Glyn Daniel), *review* by C. A. Ralegh Radford, 420
"Prelectiones Anatomiae Universalis" (William Harvey). (Lectures on the Whole of Anatomy. An annotated translation by Prof. C. D. O'Malley et *al*.), *review* by Sir Russell Brock, 523
Pre-Lumirhodopsin and the Bleaching of Visual Pigments (T. Yoshizawa and G. Wald), 1279
Preparation of Antisera to Human Follicle-stimulating Hormone (W. R. Butt, A. C. Crooke. F. J. Cunningham and A. Wolf), 388
Preparation of Carcinogenic Polynuclear Hydrocarbons labelled with Tritium by Wilzbach's Method (W. Lijinsky and H. Garcia), 688
Preparation of $[^{131}I]$-3-Monoiodotyrosine and $[^{131}I]$-3,5-Diiodotyrosine of Very High Specific Activity (W. S. Reith and W. Tampion), 180
Presence of a Phosphatido-peptide Fraction in Liver Cell Membrane and its Possible Role in the Active Transport of Amino-acids (E. Tria and O. Barnabei), 598
Presence of Iodine-127 Iodotyrosines in Extracts of Normal Human Serum (Prof. S. C. Werner and Dr. I. Radichevich), 877
Presence of Œstrogen Sulphokinase in Chick Embryonic Cartilage (J. B. Adams), 1007
Presence of Phosphate-mediated Cross-linkages in Hard Tissue Collagens (A. Veis and R. J. Schlueter), 1204
Pressure Calibration of a Tetrahedral Anvil Device (R. B. Graf and B. C. Deaton), 678
Pressure Group Politics : *The Case of the British Medical Association*. By Harry Eckstein, 111
Preston, Prof. G. B. : Appointed to the chair of Mathematics, 1252
Preston, N. W., and P. Evans : Type-specific Immunity against Intracerebral Pertussis Infection in Mice, 508
Prestwich Medal Awarded, 955
Presumed Obstacle to Mammalian Polyploidization (Yngve Melander), 152
Prevalence and Importance of Viable Spores of *Septoria* spp. in Samples of Commercial Celery Seed (P. D. Hewett), 918
Price, A. T., and J. A. Lawrie : Motion of Current Systems in the Ionosphere, 581
Price, S. A. : Fluoride, Teeth and the Analyst, 342
Price, Prof. W. C. : Fundamentals of Infrared Technology, *review*, 633
  Standardization of Spectrophotometric Data in the Near Ultraviolet, Visual and Near Infrared, *review*, 633
  Theory and Applications of Ultraviolet Spectroscopy, *review*, 633
Primaquine Sensitivity . Molecular Deficiency of Glucose-6-Phosphate Dehydrogenase in (H. N. Kirkman and B. B. Crowell), 286
Primary Productivity of Periphyton (R. G. Wetzel), 1026
Primate Anatomy : Dr. E. H. Ashton appointed reader in, 132
Pringsheim, Ernst G., and Wolfgang Wiessner : Minimum Requirements for Heterotrophic Growth, and Reserve Substance in *Beggiatoa*, 102
Probability and Statistics : Introduction to (Henry L. Alder and Edward B. Roessler), *review* by W. Brass, 1138
Probable Mechanism Regulating Water Economy of *Rhodnius prolixus* (J. A. Núñez), 312
Problems in the Communication of Scientific and Technical Information, 542
Proceedings of the 7th International Congress for Microbiological Standardization, London, 1961. (edited by A. F. B. Standfast, D. G. Evans and B. G. F. Weitz), (International Association of Microbiological Societies · Permanent Section for Microbiological Standardization), *review* by L. B. Quesnel, 1138

Proctor, J. R., and W. B. Kendrick : Unequal Weighting in Numerical Taxonomy, 716
Proctor, Dr. M. H., and Esam Moustafa Incorporation of Amino-Acid by Root Nodules of *Galega officinalis*, 262
Prodigiosin by *Serratia marcescens* : Effect of Gibberellic Acid on the Production of (P. O. Bennett and H. D. Graham), 778
Production of a Highly Tissue-specific Antiserum against a Particular Sub-fraction separated from Kidney Microsomes (T. S. Okada and A. G. Sato), 1216
Production of Liquid Drops (C Johnson), 1092
Production of Specific Hæmagglutinins in Pigs after receiving Skin Homografts (R Saison and D. G. Ingram), 296
Progestational Activity of 4-Hydroxy-17-Alpha-Acetoxyprogesterone (G. Arcari, G. Baldratti and G. Sala), 292
Progesterone in Ovaries of the Marine Teleost *Conger conger* · Œstrogens and (C Lupo and G. Chieffi), 596
Progress and Innovation in Scientific Research, 852
Progress in Ceramic Science (Dr J E Burke), Vol. 2, *review* by Dr. N. F. Astbury, 932
Progress in Inorganic Chemistry, Vol 3 (edited by F. Albert Cotton), *review* by Dr. I. R Beattie, 635
Prolactin : Immunological Investigations of Sheep (Z Laron and S. Assa), 299
Proline during Healing of Fractures : Utilization of (K. H. Ibsen *et al*), 803
Proline during Yeast Sporogenesis Accumulation of Free (C. Ramirez and J J. Miller), 722
Proline in Various Living Cells Common Pathway for Uptake of Glycine and (D. F. Evered and H G Randall), 386
Properties of Phage-neutralizing Antibodies produced by New-born Rabbits (B Pernis, I. Ghezzi and M. Turri), 807
Properties of the Separated Chains of Human γ-Globulin (Dr. S. Cohen), 253
Propylene Phenoxetol as a Fish Anæsthetic (T B. Bagenal), 1222
Prostatic Fluid : Ultracentrifugal Constituents of Human and Canine (Prof. S. Shulman *et al*), 58
Protection of the Skin Homografts by ϵ-Acetamide Caproic Acid (A. Bertelli and G Frontino), 510
Protein Chemistry · Advances in (edited by C. B Anfinsen, jun., *et al.*), Vol. 15, *review* by Dr Brian S. Hartley, 423
Protein Chemistry (including Polypeptides) : A Laboratory Manual of Analytical Methods of (edited by P. Alexander and R. J. Black), Vol 3, *review* by Dr. D. T. Elmore, 113
Protein Digestibility and Ingestion (J. P. Greaves), 499
α_2-Protein Fraction : Effect of Antibody Production of Injection of an (J. F. Mowbray), 1019
Protein from a Starch-'Pevikon C-870' Gel . Improved Recoveries of (V. Bocci), 491
Protein in Ethanol Solubility of Bean Leaf (David Racusen and Murray Foote), 697
Protein Nutrition and Radiation Damage in Mice (S Tanaka, A. Nukazawa, H. Yoshikawa and Y. Yoneyama), 305
Protein Synthesis · Ribosomal Aggregate Engaged in, Characterization of the Ergosome (Dr. F. O. Wettstein *et al.*), 430
 Structural Requirements for Puromycin Inhibition of (Dr. Daniel Nathans and Dr. Amos Neidle), 1076
Protein–Vitamin Concentrates from Petroleum · Biosynthesis of (A. Champagnat *et al.*), 13
Proteins : Nomenclature of Serum (P. Grabar), 692
 Post-mortem Lability of Skeletal Muscle (R K. Scopes and R. A. Lawrie), 1202
 Repression of Delayed Hypersensitivity to Conjugated Serum Albumin during Immune Paralysis induced in Guinea Pig by Heterologous (T. Neveu *et al.*), 1023
 Starch-gel Electrophoresis of Pig Serum (R. K Scopes), 1201
Proteins and Amines with Chloranil · Interaction of Amino-Acids (Dr. J. B. Birks and Dr. M A. Slifkin), 42
Proteins by the Biuret Reaction . Interference by Ammonium Sulphate with the Estimation of (P. G Stanley), 1108
Proteolipid A extracted from Human Brain · Skin Reactions in Neurological Patients after Intracutaneous Administration of (D. Bohme *et al.*), 609
Proteolytic Activation of Glucose-6-phosphatase in Normal, Diabetic and Hepatomic Rat Livers (E. Heise and M Gorlich), 1311
Proteolytic Enzymes · Immunoelectrophoretic Characterization of (V. Raunio and O. Gabriel), 1012
Prothrombin (Prof. Walter H Seegers), *review* by Dr R. G. MacFarlane, 1136
Protomyces inundatus Cultures Nucleic Acids and Other Characteristics in Biotin deficient and Normal (L. R. G. Valadon), 96
Proton in Humic Acids : Solvation of the (D. Schwartz and L Asfeld), 177
Proton Magnetic Resonance Investigation of Enzyme–Coenzyme Complexes (Oleg Jardetzky, Norma G. Wade and James J. Fischer), 183
Protozoon *Crithidia* (*Strigomonas*) *oncopelti* : Deoxyribonucleic Acid Type attributable to a Bacterial Endosymbiote in the (J Marmur *et al.*), 1228
Providence Strains and the Host-range of Providence Bacteriophages : Lysogency in (J. N Coetzee), 515
Provisions for University Expansion in Britain, 1, 24
Prowse, G. A. · Introductions of Exotic Fish, 1123
Prozesky, O. P. M. : Body Temperature of Birds in Relation to Nesting Habits, 401
Pseudo-Quadrivalents in Autotetraploid Rice (J. Bouharmont), 410
Pseudomonas saccharophila : Cytochromes of (D. H Bone), 517
Pseudomonas tabaci on the Metabolism of Starch in Tobacco Leaves : Effect of (L. Lovrekovich *et al.*), 917
Pseudomonas testosteroni · Alteration of Steroid Dehydrogenase Synthesis in a Mutant of (J. D. Teller and A. M. Bongiovanni), 1112
Psychiatric Research in Britain, 749
Psychologie : Phänomenologische (Von Edmund Husserl. Herausgegeben von Walter Biemel). Husserliana, Band 9, *review* by P. I G. Rawlins, 419
Psychology . J W. T Richards appointed lecturer in, 132
Psychology in Arid Conditions : Environmental Physiology and (Dr. C. S Leithead), 1057
Psychotomimetic Agents on Membranes : A Possible Mechanism of Action of Calcium and some (L. G. Abood *et al.*), 367
Ptak, Marius, *et al.* : Examination of Optically Excited Amino-acids by Electron Spin Resonance at Very Low Temperature, 1105
Public Health Laboratory Service Board : Prof. J. W. Howie appointed Director, 749
Publishers · Learned Societies as (A V. S de Reuck), 426
Pugh, S. F. : Nuclear Reactor Fuel Elements : Metallurgy and Fabrication, *review*, 425
Pugwash Conferences : *Science and World Affairs* History of the (Prof. J. Rotblat), 1033
Pulling, M. J. L. : Appointed Deputy Director of Engineering (B B.C), 338
Pulsed Gaseous Maser (H. A. H Boot and D. M. Clunie), 173
Purification of Human Growth Hormone on 'Sephadex G-200' (Ralph A. Reisfeld, Barbara G. Hallows, Donald E. Williams, Norman G. Brink and Sanford L. Steelman), 1206
Puromycin . Inhibition of the Biological Action of Thyroid Hormones by Actinomycin *D* and (Dr. J. R. Tata), 1167
Puromycin Inhibition of Protein Synthesis : Structural Requirements for (Dr. Daniel Nathans and Dr. Amos Neidle), 1076
Puromycin on the Replication of Western Equine Encephalitis and Poliomyelitis Viruses · Effect of (Dr. E. Wecker), 1277
Purple Sea Urchins to Variations in Temperature and Light : Response of the Testes of (R. A. Boolootian), 403
Purves, P. E. . Locomotion in Whales, 334
Pyrazine Derivatives from Cyclic Dipeptides : Dehydropeptide Production in the Radiolysis of Solid Peptides : A Radiolytic Synthesis of (M. Kland-English and W. M. Garrison), 895
Pyridine Nucleotide in the Presence of Peroxidase : Interaction of Œstrogens labelled with Carbon-14 with (P. H Jellinck and Louise Irwin), 1107
Pyridine–Dinucleotides Catalysed by Bovine Milk Xanthine Oxidase Oxidations and Transhydrogenations involving (Dr. D. A Gilbert), 1066
Pyromellitic Acid : Polycarboxylic and Phosphonitrilic Acids as Radioprotectors : Effectiveness of (J. H. Barnes and J. St L. Philpot), 248
Pyrrolizidine Alkaloids in Rumen Liquor . Vitamin B_{12} and the Detoxification of Hepatotoxic (A T Dick *et al.*), 207
Pythium de baryanum Hesse and its Probable Significance : Fine Structure of (Lilian E. Hawker), 618

QUANTITATIVE Determination of Oxygen-18 by Activation Analysis (D. E Solberg, J. A Wethington, jun., and T. F. Parkinson), 611
Qualitative Differences in the Mechanism of Complement Fixation (F. Peetoom, K W. Pondman, M. van der Hart and J. J. van Loghem), 911
Quantitative Differential Thermal Analysis : Heats and Rates of Solid-Liquid Transitions (Dr. D. M. Speros and R. L. Woodhouse), 1261
Quantitative Histochemistry of Succinate Dehydrogenase in Tissue Sections (G. R. N. Jones, A. J. Maple, E. K Aves, J. Chayen and Prof. G. J. Cunningham), 568
Quantitative Technique for Uniform Tumour Implantation by Trocar in Gelfoam (B. Gottfried, M. Padnos and N. Molomut), 1309
Quantum Mechanics : Representation of a Group in Relativistic (M. C. Goodall), 585
Quartz Crystals at the Transformation Temperature : Deformation of (A. C. D. Chaklader), 791
Quartz Particles : Effect of Grinding on (J. H Talbot and E. B. Kempis), 66
Quartz, Provenance and Sedimentation : Clastic (Dr. J. T. Greensmith), 345
Quartz, Titanium Colour Centres in Rose (P. M. Wright *et al*), 246
Quasi-continuous Output from a Ruby Optical Maser (M. S Lipsett and Dr. L. Mandel), 547
Queen Maud Land, Antarctica : Geographical Variations of Oxygen-18/Oxygen-16 Ratio in Surface Snow and Ice from (R. Gonfiantini *et al.*), 1096
'Queen Substance' (9-oxodec-*trans*-2-enoic acid) on Ovary Development of the Housefly, *Musca domestica* L. Effect of Synthetic (J. K. Nayar), 923
Queensland Institute of Medical Research . Seventeenth Annual Report, 341
Quesnel, L. B. · Proceedings of the 7th International Congress for Microbiological Standardization, London, 1961. (International Association of Microbiological Societies : Permanent Section for Microbiological Standardization), *review*, 1138
Quraishi, M. S., and M. Arthur : Mating Behaviour of *Anopheles stephensi*, 312

RABBIT . Maternal Behaviour in the : Effects of Environmental Variation (Victor H. Denenberg, *et al.*), 161
Rabbit Foetus on Foetal Cholesterol Metabolism : Effect of Total Thyroidectomy in the (J. G. Bearn and T. R. E. Pilkington), 1302
Rabbit Serum Proteins, using High-resolution Porath Zone Electrophoresis and Starch-gel Electrophoresis : Combination Analysis of (W. A. Hemmings and R. E. Jones), 695
Rabbit Spleen Cell Cultures Transfer of Stimulation of Deoxyribonucleic Acid Synthesis in Antigen-stimulated (R. W Dutton and G. Harris), 608
Rabbits Effect of Fluoroacetate on Uptake of Yttrium-91 in (Jill Dearnaley), 1218
 Glycoprotein Excretion following the Injection of Papain into (A. J. Anderson *et al.*), 707
 Properties of Phage-neutralizing Antibodies produced by New-born (B. Pernis *et al.*), 807
Rabbits after Sympathetic Denervation · Supersensitivity of Aqueous Outflow Resistance in (M. L. Sears and T. E. Sherk), 387
Rabbits and Guinea Pigs : Effect of Hypertonic Saline Injections on the Secretion of Thyroid Hormones in (G. Feuer), 1176
Rabbitt, P M. A. : Information Load and Discriminability, 726
Rabotti, G., and I. Iossifides . Factors modifying the Post-Radiation Effects of Homologous Spleen, 199
Race, Dr. R. R., *et al.* : Evidence that the Xg Blood Group Genes are on the Short Arm of the X Chromosome, 648
Racusen, David, and Murray Foote : Solubility of Bean Leaf Protein in Ethanol, 697
Radar : Airborne (Donald J. Povejsil, *et al.*) (Principles of Guided Missile Design), *review* by R. Aspinall, 220
Radar and Refractometer Soundings of the Troposphere : Simultaneous (J. A. Lane and R. W. Meadows), 35
Radar Research Establishment : Military and Civil Systems Department, 436
Radcliffe Committee, 930
Radiation · Factors modifying the Post-Radiation Effects of Homologous Spleen (G. Rabotti and I. Iossifides), 199
Radiation Chimeras : Influence of Excess of Antigen on Immunological Tolerance in (O B. Zaalberg *et al*), 300
Radiation Damage Effects in Barium Chromate Crystals : Possible (T. Adamski and L Trojanowski), 1005
Radiation Damage in Mice : Protein Nutrition and (S. Tanaka *et al.*), 305
Radiation Environment : The Natural, meeting to be held at the William Marsh Rice University, Houston, 652
38-Mc/s Radiation from Jupiter (C. H Barrow), 580
Radiation Hazards · *Code of Practice for* (fourth edition. Imperial College of Science and Technology), 849
γ-Radiation in Rats : Experimental Oxidation of Hæmoglobin Effect of Repeated Whole-body (W. K. Metcalf), 709
Radiation Injury : Recovery from . A Proposed Mechanism (Dr. R. F. Kallman), 557
Radiation Nephritis to Administration of L-Triiodothyronine : Unfavourable Response of (W. L. Caldwell *et al.*), 200
Radiation Patterns in the Lower Ionosphere and Fresnel Zones for Elevated Antennas Over a Spherical Earth National Bureau of Standards Monograph 38, 130

Radiation Protection by Cyanide of both Rats and Mice (Jack Shubert and J. F. Markley), 399
Radiation Research : Second International Congress of, held in Harrogate, 1962, 221
Radiation-induced Ionic Reactions : Cyclopentadiene Polymerization (T. H. Bates), 1101
Radiation-Mortality Reducing Factor from Spleen : Isolation of a (S. Katz and the late F. Ellinger), 397
Radichevich, Dr. I., and Prof. S. C. Werner Presence of Iodine-127 Iodotyrosines in Extracts of Normal Human Serum, 877
Radioactive Barium : Estimation of Small Amounts of Sulphate by Precipitation with (D Picou and J. C. Waterlow), 1103
Radioactive Fall-Out Particles : Fractionation Phenomena in Highly (T. Mamuro *et al.*), 964
Radioactive Marking Ink (J. E. Gardiner), 414
Radioactive Solutions · Storage of Standardized (J H. Harley *et al.*), 1230
Radioactive Sulphur after Oral Administration to the Rat of a Water-Insoluble Fraction of Sulphur-35-labelled Thermal Amino-Acid Copolymer : Distribution of (F. Knappen and G. Krampitz), 289
Radioactivity in Human Diet, 241
Radioactivity in Large Marine Plankton as a Function of Surface Area (Prof. C. Osterberg, L. Small and L. Hubbard), 883
Radioactivity in Solid Media . Stability of Glasses and Glazes : Fixation of (Dr. Galen R. Frysinger and Dr. Henry C. Thomas), 352
Radioactivity of Biological Materials from Brazilian Areas Rich in Thorium Compounds (Dr. E. Penna-Franca and O. Gomes de Freitas), 1062
Radiobiological Institute of the Organization for Health Research TNO, Holland (Dr. L. M. van Putten), 1157
Radiobiology : Fundamentals of (Z. M. Bacq and Peter Alexander), revised, second edition, *review* by Dr. E. V. Hulse, 931
Radiochemistry : Advances in Inorganic Chemistry and, Vol. 4 (edited by Prof. H. J. Emeléus and Dr. A. G. Sharpe), *review* by Dr. D. W. A. Sharp, 325
Radio-frequency Fields on the Zeta-potential of a Colloidal Suspension : Effect of (J. H. Heller *et al.*), 997
Radiogenic Isotopes of Lead Discrepancy in Age-determination Involving (A. Masuda), 892
Radio-iodine Excretion in the Urine of Intact Stilboestrol-treated Guinea Pigs : Sex Differences in the Pattern of (A. Slebodziński), 801
Radio-iodine from Tellurium by Means of Column Chromatography · Separation of (N. Getoff and W. Parker), 278
γ-Radiolysis of Liquid Acetone · Some Products of the (J Kučera), 279
Radiometric Precipitation · Measurement of Small Quantities of Calcium by (J. N. Kudahl), 1199
Radio Observations of Jupiter during 1962 (J. A. Gledhill, G. M. Gruber and M. C. Bosch), 474
Radio Protectors · Polycarboxylic and Phosphonitrilic Acids as : Effectiveness of Pyromellitic Acid (J. H. Barnes and J. St. L. Philpot), 248
Radio Pulses from a Satellite : Some Preliminary Results of Sounding of the Top Side of the Ionosphere by (E. S. Warren), 636
Radiosensitive Organs after Whole-body Irradiation in Rats : Decreased Incorporation of Phosphorus-32 in (Z Dienstbier and F. Vítek), 198
Radio Source 3C 273 by the Method of Lunar Occultations : Investigation of the (C. Hazard *et al.*), 1037
  Absolute Energy Distribution in the Optical Spectrum of 3C 273 (Dr. J. B. Oke), 1040
  3C 273 . A Star-like Object with Large Red-Shift (Dr. M. Schmidt), 1040
  3C 48 : Red-Shift of the Unusual (Dr. Jesse L. Greenstein and Dr. Thomas A. Matthews), 1041
Radio Sources : Nature of Strong (Prof. F. Hoyle and Prof. William A. Fowler), 533
  Polarization and Classification of (Dr. R. D. Davies and G. L. Verschuur), 32
Radio Sources and Faraday Rotation Effects in the Galaxy : Polarization of (F. F Gardner and J B. Whiteoak), 1162
Radiostrontium as influenced by Tetracycline . Retention in the Skeleton of (A. Catsch), 302
Radio Telescope : Modification of the Design of the Proposed Benelux (Dr. W. N. Christiansen *et al.*), 940
Radio-Transit Telescopes steerable in Azimuth (P. D. Usher), 170
Radio Wave Propagation . Effect of the U.S. High-altitude Nuclear Explosion on (P. Roben *et al.*), 887
Radium-226 by the Freshwater Gastropod *Lymnaea stagnalis* L. : Accumulation of (O. Van der Borght), 612
Radon Concentration in the Air above the Atlantic Ocean : Meteorological Conditions Dependence of (J. Fontan *et al*), 583
Raffkina, L. I , and Dr. George J. Svet-Moldavsky Thymus-Lymphatic Nodes Interrelations Following Injection of Freund's Adjuvant, 52

  Effect of Adrenalectomy on Histamine Metabolism in the (J. M. Telford), 600
  Effect of Carbon Tetrachloride Intoxication on the Activity of Enzymes of the Urea Cycle in the Liver of the (F. Rossi and Patricia McLean), 1207
  Effect of Tetanus on the Parental Behaviour in the (A. A. Fedinec) 497
  Histamine-liberating Effect of Magnesium Deficiency in the (P. Bois *et al.*), 501
  Influence of the Œstrous Cycle and Ovariectomy on the Phospholipid Content of the Pineal Gland in the (J. Zweens), 1114
  Nuclear Deoxyribonucleic Acid Content in Corona Radiata of the Ovary of the (D. Vandekerckhove), 190
  Relation between Calcium Ions and the Action of Serotonin on a Fundus Strip of the (J. Kozák and N Lang), 293
Rat Hemidiaphragm Assay of Insulin . A Significant Variable in the (J. Bingle) 595
Rat Intestinal Mucosa and *Penicillium digitatum* : Ethylene Production by Subcellular Particles from Rat Liver (Dr. G. Ram Chandra and Prof. Mary Spencer), 366
Rat Intestinal Mucosa during Fat Absorption : Phospholipid Composition and Turnover in (M. I. Gurr *et al.*), 79
Rat Intestine *in vitro* : Glucuronide Formation and Transport of Various Compounds by Gunn (I. M. Arias *et al.*), 1109
Rat Liver, Rat Intestinal Mucosa and *Penicillium digitatum* . Ethylene Production by Subcellular Particles from (Dr. G. Ram Chandra and Prof. Mary Spencer), 366
Rat Livers : Proteolytic Activation of Glucose-6-phosphatase in Normal, Diabetic and Hepatomic (E. Heise and M. Gorlich), 1311
Rat of a Water-insoluble Fraction of Sulphur-35-labelled Thermal Amino-Acid Copolymer : Distribution of Radioactive Sulphur after Oral Administration to the (F. Knappen and G. Krampitz), 289
Rat Tissues : Formation of Histamine in (J. M. Telford), 701
Rat with Norethynodrel : Termination of Pregnancy in the (B. K. Davis), 308
Rats : Antiserum Inhibition of the Œstrous Cycle in Normal (W. P. Young *et al.*), 1117
  Blood Coagulation in Arteriosclerotic (Prof. B. C. Wexler and Dr. M. J. Epstein), 159
  Changes in the Excretion of Sodium by Saliva after Whole-body Irradiation in (J. Ondráčková *et al.*), 915
  Decreased Incorporation of Phosphorus-32 in Radiosensitive Organs after Whole-body Irradiation in (Z. Dienstbier and F. Vítek), 198
  Effect of Œstradiol on Spinal Cord Convulsions in Developing (A. Vernadakis and P. S. Timiras), 906
  Effect of Thyroid Irradiation on the Release of Labelled Protein-bound Iodine in (M. Anbar and M. Inbar), 302
  Experimental Oxidation of Hæmoglobin : Effect of Repeated Whole-body γ-Radiation in (W. K Metcalf), 709
  Glucose-6-phosphate Dehydrogenase and Aldolase in Lenses of Lactose-fed (I. Korc and M. Calcagno), 690
  Manipulation of Salt Solution—Fresh Water Drinking Regimen and Eating Behaviour in (H. Kaunitz *et al.*), 457
  Measurements of Tubular Fluid *p*H *in vivo* in (Norman Bank and Hagop S. Aynedjian), 185
  Plasma Triglycerides and Thrombosis in (L. Bizzi *et al.*), 195
Rats and Mice : Ineffectiveness of Autotransplantation on Growth of the Methylcholanthrene Sarcoma in (M. Matsuyama *et al.*), 805
Rats and Mice : Radiation Protection by Cyanide of both (J. Schubert and J. F. Markley), 399
Rats injected with Homologous Heart Tissue : Development of the Fœtus in Female (L. P. Cawley *et al.*), 1307
Rat's Intestine · Transport of Potassium Ions in the (A. Gilman *et al.*), 1210
Rats of Two Different Ages : Adipose Tissue Lipoprotein Lipase Activity in (C. Chlouverakis, 196, 1103), *erratum*, 341
Rats previously injected with Placental Tissue · Growth of Transplantable Cancer in (R. M. Wynn), 606
Rate of Flotation in a Hallimond Tube (Dr. C W. Nutt, Dr. M. Kemp and J. Weston), 40
Rate of Restitution and Self-regulation of Contractility in Mammalian Heart Muscle (V. Kruta and P. Bravený), 905
Rates of Calcium Carbonate Deposition by Deep-Sea Organisms, Molluscs and the Coral-Algae Association (K. K. Turekian), 277
Ratio Adenosine Triphosphate/Adenosine Diphosphate in Platelet-rich Plasma in Hæmorrhagic Disorders (Von Willebrand and Glanzmann Disease), (J. P. Caen), 504
Raunio. V., and O. Gabriel : Immunoelectrophoretic Characterization of Proteolytic Enzymes, 1012
Rauss, J., *et al.* : Effect of an Exogenous Interferon on Experimental Influenza Virus Infection and Interferon Production in White Mice, 821
Raven, Robert S., *et al.* : Airborne Radar (Principles of Guided Missile Design), *review* by R. Aspinall, 220
Rawlins, F. I. G. : Biology and the Nature of Man : Based upon the Riddell Memorial Lectures Thirty-third Series, *review*, 114
  Phänomenologische Psychologie : Vorlesungens Sommersemester 1925. Husserliana, Band 9, *review*, 419
Rawlins, S. L., and D. N. Moss : Concentration of Carbon Dioxide inside Leaves, 1320
Ray, J. W. : Insecticide absorbed by the Central Nervous System of Susceptible and Resistant Cockroaches exposed to Dieldrin, 1226
Raynor, J. B., and J. F. Sackman : Oxidation of Plutonium in Moist Air and Argon, 587
Rayon · The Beginning of (Edwin J. Beer), *review* by L. A. Wiseman, 525
Reaction between Monocalcium Phosphate and Calcium Carbonate (S. Larsen, D. J. Parton, and I.-L. Svensson), 317
Reaction of Lime with Ferric Oxide (A. K. Chatterji and T. C. Phatak), 350
Reaction of Phenyl Isocyanate with 2,3-Epoxy Propyl Phenyl Ether (Phenyl Glycidyl Ether), (D. A. Smith), 285
Reaction of Platinum and Boron under Pressure (E. D. Whitney and R. F. Giese, Jun.), 1293

Reaction of Sulphoquinovose from Red-Clover Lipids with Anthrone (R. O. Weenink), 62
Reactivity of Deformed Metal Surfaces (R. B. Campbell), 374
Reactor at Full Power at Buchanan, New York, 849
Reams, G. B.: Use of *Cyclophosphamide* in an Attempt to Modify the Canine Renal Homograft Response, 713
Rearing of Cuttlefishes and Squids (Sang Choe and Y. Ohshima), 307

Strontium-90 and Caesium-137 in Japanese Leafy Vegetables due to the Russian Nuclear Tests, 1961 : Increase of (R. Ichikawa and M. Eto), 509
Strontium-90 Daily : Reproductive Performance of Female Miniature Swine Ingesting (R. O. McClellan et *al.*), 670
Strontium-90 injected into Male Mice : Genetic Effects of (K. G. Luning et *al.*), 304
Strontium in Blood : Binding of (T. E. F. Carr et *al*), 710
Strontium Method : Age Determination of some Yugoslav Granites and Granodiorites by the Rubidium/ (Z. Cervenjak et *al.*), 893
Structural Requirements for Puromycin Inhibition of Protein Synthesis (Dr. Daniel Nathans and Dr. Amos Neidle), 1076
Structure and Biosynthesis of Macromolecules (edited by D. J. Bell and J. K. Grant), (Biochemical Society Symposium No. 21, London 1961), *review* by Dr. H. Gutfreund, 327
Structure of Red-Cell Ghosts and the Effect of Saponin Treatment (F. Husson and Vittorio Luzzati), 822
Structure of Ripple Marks (Prof. J. E. Hemingway and A. M. Clarke), 550
Struve, Dr. Otto : The Universe (Karl Taylor Compton Lectures 1959), *review* by Sir Bernard Lovell, 216
Stryer, L., et *al.* : Axial Period of Fibrinogen and Fibrin, 793
Stuart, F., et *al.* : Isolation and Maintenance of Single Spore Lines of *Peronospora tabacina* (Adam.), 515
Stubbens, E. C. : *Obituary*, 19
Stubbs, L. L., and R. G. Grogan : Lettuce Necrotic Yellows Virus, 1229
Studies in Individual Differences : The Search for Intelligence (edited by James J. Jenkins and Donald G. Patterson), *review* by Dr. Liam Hudson, 1238
Studies in the Tertiary Flora of Spitsbergen · With Notes on Tertiary Floras o Ellesmere Island, Greenland, and Iceland—a Palynological Investigation. (Svein Manum), (Skrifter Nr. 125), *review* by Dr. R. G. West, 324
Sturley, Dr. K. R. : Appointed Chief Engineer, external broadcasting (B B.C.), 339
Sturtevant, A. H. : Genetics and Evolution : Selected papers of, *review* by Prof. C. D. Darlington, 830
Su, C. K., and W. W. Spink : Failure to protect Mice against Endotoxin with Snake Venom, 88
Sub-sieve Sizing by Sedimentation Balance (C. C. Harris and A. Jowett), 1192
Successful Development of Chick Embryos Nourished by Yolk-Sac Perfusion with Calcium-low Media (C R. Grau, N. E. Walker, H. I. Fritz and S. M. Peters), 257
Succession of Nematophagous Fungi during the Decomposition of Organic Matter in the Soil (R. C Cooke), 205
Succinate Dehydrogenase in Tissue Sections · Quantitative Histochemistry of (G. R. N. Jones et *al.*), 568
Succinic Dehydrogenase Catalysed Reaction : Mechanism of the (Prof. O. Gawron, et *al.*), 1270
Succinic Dehydrogenases Activity and Oxidative Phosphorylation of the Mitochondria in the Crystalline Lens of Bovines (N. Virmaux and P. Mandel), 792
Sudden Changes in Amplitude and Phase of the Very-Low-Frequency Signal from Station *GBR* at Salisbury, South Australia (P. Rohan, L. L. Anderson and D. J. Cooke), 783
Sugar Beet Crops : Spread of Yellows Virus by *Myzus persicae* in (C. R. Ribbands), 624
Sugar Beet infected with Yellowing Viruses : Specific Lipids produced by (V. H. Booth and G. E. Russell), 1328
Sugar Stability : Non-Enzymatic Browning Reactions : Consideration of (H. S. Burton and D. J. McWeeny), 266
Sugden, Dr. T. M. : Elected a Fellow of the Royal Society, 1251
Suits, Gwynn H., et *al.* : Fundamentals of Infrared Technology, *review* by Prof. W. C. Price, 633
Sulphate by Precipitation with Radioactive Barium : Estimation of Small Amounts of (D. Picou and J. C. Waterlow), 1103
Sulphides in Sphalerite : Multiple Solid Solution on (L. J Lawrence), 171
Sulphoquinovose from Red-Clover Lipids with Anthrone : Reaction of (R. O. Weenink), 62

Sulphoxides on Paper Chromatograms: Sensitive Qualitative Test for (J. F. Thompson, W. N. Arnold and C. J. Morris), 380
Sulphur-35-labelled Thermal Amino-Acid Copolymer: Distribution of Radioactive Sulphur after Oral Administration to the Rat of a Water-insoluble Fraction of (F. Knappen and G. Krampitz), 289
Sulphur-35 in Wool by Liquid-Scintillation Counting: Assay of Tritium, Carbon-14 and (A. M. Downes and A. R. Till), 449
Sulphydryl Groups Essential for the Penicillinase Activity of *Aerobacter cloacae* (J. T. Smith), 900
Summers, L. A., and J. A. W. Turner: Fungitoxicity of 2,4-Dichloro-3,5-dinitrobenzoates, 495
Sumner, Dr. W. L.: Frédéric Joliot-Curie et l'Energie Atomique, *review*, 632
Sunthankar, S. V., *et al.* (edited by): Recent Progress in the Chemistry of Natural and Synthetic Colouring Matters and Related Fields, *review* by Dr. R. Livingstone, 1237
Supersensitivity of Aqueous Outflow Resistance in Rabbits after Sympathetic Denervation (M. L. Sears and T. E. Sherk), 387
Supersonic Engineering: A Symposium held at the Royal College of Advanced Technology, Salford (edited by J. T. Henshaw), *review* by Dr. J. K. Harvey, 525
Suppression of Experimental Allergic Encephalomyelitis by Cytotoxic Drugs (D. B. Calne and S. Leibowitz), 1309
Suppression of Infections Resulting from a Deoxyribonucleic Acid Virus (Vaccinia) by Systemic Administration of 5-IODO-2′-Deoxyuridine (P. Calabresi, R. W. McCollum and Prof. A. D. Welch), 767
Surfactants: Breaking Foams produced by Ionic (F. Sebba), 1195
Susceptibility Anisotropy Measurements on some Silurian Siltstones (N. Hamilton), 170
Suter, P. J., and J. MacMillan: Thin Layer Chromatography of the Gibberellins, 790
Sutherland, Dr. N. S.: Shape Discrimination and Receptive Fields, 118
Sutter Blood Group System: Anti-Js^b, the Expected Antithetical Antibody of the (R. H. Walker *et al.*), 295

Transfer of Stimulation of Deoxyribonucleic Acid Synthesis in Antigen-stimulated Rabbit Spleen Cell Cultures (R. W. Dutton and G. Harris), 608
Transhydrogenations involving Pyridine-Dinucleotides Catalysed by Bovine Milk Xanthine Oxidase : Oxidations and (Dr. D. A. Gilbert), 1066
Transient Circuit Analysis (Prof. Y. H. Ku), *review* by Prof. A. H. M. Arnold, 422
Transmission of anti-*Brucella abortus* Agglutinins across the Gut in Young Mice (I. G. Morris), 813
Transmission of Noradrenaline across the Human Placenta (M. Sandler, C. R. J. Ruthven, S. F. Contractor, Carl Wood, R. T. Booth and J. H. M. Pinkerton), 598
Transplantable Mammary Adenocarcinoma (*72J*) and Spontaneous Mouse Breast Tumours : Effect of a New Anticancer Agent, 1,4-Dimethyl-1,4-Diphenyl-2-Tetrazene, on a (A. W. Vogel *et al.*), 85
Transplantation : Ciba Foundation Symposium on (edited by G. E. W. Wolstenholme and Margaret P. Cameron), *review* by W. J. Dempster, 1237
Transplanted Mouse Marrow Cells : Cytological Demonstration of the Clonal Nature of Spleen Colonies Derived from (Dr. A. J. Becker *et al.*), 452
Transport : Prof. C. D. Buchanan appointed to the chair of, 1153
Transport of Pebbles over Smooth Ice in Antarctica (H. W. Wellman), 681
Transport of Potassium Ions in the Rat's Intestine (A. Gilman, E. Koelle and J. M. Ritchie), 1210
Transpositions of Modulator in Maize into Divided and Undivided Chromosome Segments (Irwin M. Greenblatt and R. Alexander Brink), 412
Trapani, I. L., *et al.* : Electrophoretic Analysis of Serum and Pleuroperitoneal Fluid Proteins and Antibody From Guinea Pigs, 704
Trauring, Mitchell : Automatic Comparison of Finger-Ridge Patterns, 938
Trautwein, W., and H G. Haas : Increase of Sodium Efflux induced by Epinephrine in the Heart of the Frog, 80
Treatise on Analytical Chemistry, Part 2, Vol. 7 (edited by I M. Kolthoff and Philip J Elving), *review* by Prof. R. Belcher, 832
Trees : Effect of Gibberellic Acid on Flowering of Apple (R. Marcelle and C. Sironval), 405
  Possible Presence of a Phytotoxin in Red-ring Infected (L. C. Goberdhan), 619
Trees, Dr. Richard E. : *Obituary* of, 338
Trematode Parasites : Oysters killed by (R. H. Millar), 616
Trend Committee, 929
Tria, E., and O. Barnabei : Presence of a Phosphatidopeptide Fraction in Liver Cell Membrane and its Possible Role in the Active Transport of Amino-acids, 598
β-Tricaprin : Crystal Structure of (L. H. Jensen and A. J. Mabis), 681
Trichomycetes from Californian Mosquitoes : Axenic Culture in Two (Truman B. Clark *et al.*), 208
3 : 5 : 3′-triiodothyroacetic Acid on the *in vitro* Oxygen Uptake of Leucocytes of Hypopituitary Patients : Effect of (I. P. C. Murray and S. K. Bisset), 1209
L-Triiodothyronine : Unfavourable Response of Radiation Nephritis to Administration of (W. L. Caldwell *et al.*), 200
Triphospho-pyridine Nucleotide Dehydrogenase Isozymes on an Agar-gel Plate : Visualization of Different Diphospho- and (G. Broun and S. Avrameas), 1208
Tritiation by the Wilzbach Method : Occurrence of Configurational Inversion during (S. J. Angyal *et al.*), 485
Tritium by Wilzbach's Method : Preparation of Carcinogenic Polynuclear Hydrocarbons labelled with (W. Lijinsky and H. Garcia), 688
Tritium, Carbon-14 and Sulphur-35 in Wool by Liquid-Scintillation Counting : Assay of (A. M. Downes and A. R. Till), 449
Tritium in Iron Meteorites : Low Concentration of (Murry A. Tamers), 276
Tritium-Labelled Organic Compounds : Decomposition of (Dr. E. Anthony Evans and F. G. Stanford), 551
Trocar in Gel-foam : Quantitative Technique for Uniform Tumour Implantation by (B. Gottfried *et al.*), 1309
Troiano, A. R., and J. L. Mihelich : Delayed Failure in a Hydrogenated Face-centred Cubic Alloy of Nickel, 996

Trojanowski, L., and T. Adamski: Possible Radiation Damage Effects in Barium Chromate Crystals, 1005
Tropical Haematology (G. Van Ros), 546
Tropical Parasitology (Prof. J. F. A. Sprent), 1256
Tropical Rain-Forest Environment: Soil Nitrogen Accretion under Different Covers in a (E. O. Jalyebo and A. W. Moore), 317
Troposphere: Simultaneous Radar and Refractometer Soundings of the (J. A. Lane and R. W. Meadows), 35
Trout (Sea): Occurrence of *Discocotyle sagittata* on (D. J. Slinn), 306
Trypanosoma suis Ochmann in the Central African Forest: Wild Pigs as Hosts of *Glossina vanhoofi* Henrard and (L. van den Berghe and A. J. Zaghi), 1126
Trypsin in a Defined Medium: Culture of Strain *L* Cells in Suspension: Replacement of Polymer by Traces of (Dr. R. Sinclair et *al.*), 982
Tryptamine in the Blood and Urine of a Patient with a Carcinoid Tumour (D. Eccleston, T. B. B. Crawford and G. W. Ashcroft), 502
Tryptophan–Nicotinic Acid Metabolism in Subjects recently or long since recovered from Viral Hepatitis (M. Piazza and F. Tancredi), 903
Tsetse in the Environment of Ancient Man in Southern Rhodesia (J. P. Glasgow), 414
Tsuluca, V., and A. L. Copley: Antagonistic Action of Urokinase to Bradykinin- and Plasminogen-induced Capillary Permeability, 294
Tube-feet of Ophiuroids: Extension and Retraction of the (J. B. Buchanan and J. D. Woodley), 616
Tubular Fluid pH *in vivo* in Rats: Measurements of (Norman Bank and Hagop S. Aynedjian), 185
Tubularia crocea L. Agassiz in British Waters (W. J. Rees), 1223
Tulloh, N. M.: Relation between Carcass Composition and Live Weight of Sheep, 809
Tumour Cells: Electrophoretic Mobility of Human (P. S. Vassar), 1215
Tumour Cells: Immunization against Ehrlich's Ascites Carcinoma with Streptomycin Complexes from (W. J. Polgase), 301
Tumour Implantation by Trocar in Gel-foam: Quantitative Technique for Uniform (B. Gottfried et *al.*), 1309
Tumour Induction in C_3H and Swiss *ICR* Mice by Tissue Culture Preparations of Polyoma Virus (R. Wallace, E. L. Jungherr and A. W. Moyer), 298
Tumour-bearing Rats which is Deleterious to Cells in Tissue Culture: A Factor in the Serum of (J. Watts), 196
Tumours: Effect of a New Anticancer Agent, 1,4-Dimethyl-1,4-Diphenyl-2-Tetrazene, on a Transplantable Mammary Adenocarcinoma (72J) and Spontaneous Mouse Breast (A. W. Vogel et *al.*), 85
    Non-specific Precipitation Patterns obtained in Double Diffusion between Serum and Extracts of Normal Organs and (C. Deckers and J. Maisin), 397
Tumours in *BALB/c* Female Mice Foster-nursed by *C3H* and RIII Mothers: Characters of Mammary (F. Squartini et *al.*), 505
Turbidity Current Sediment: Size Analyses of (Charlotte Davidson and M. J. Keen), 372
Turekian, K. K.: Rates of Calcium Carbonate Deposition by Deep-Sea Organisms, Molluscs and the Coral–Algae Association, 277
Turkeys: Dimetridazole: Absorption, Excretion and Metabolism in (G. L. Law et *al.*), 1024
Turner, Brian, et *al.*: A Ring Chromosome in Man, 102
Turner, D. T., and A. Pecerlin: Rheopexy in Dilute Polymer Solutions at Low Shear Gradients, 488

Universe, The (Dr. Otto Struve), (The Karl Taylor Compton Lectures 1959), *review* by Sir Bernard Lovell, 216
Universities: The Expanding, 848
Universities and Colleges in Great Britain: Government Support for, 24
Universities and Education Today. The Lindsay Memorial Lectures given at the University College of North Staffordshire, No. 2. By Prof. Herbert Butterfield, 2
Universities and the Community in South Africa (Dr. T. E. W. Schumann), (Substance of an address delivered at the opening of the Academic Year of the University of South Africa), 1139
Universities Federation for Animal Welfare and the British Small Animals Veterinary Association, meeting on "Small Animal Anaesthesia", 652
University College, London: Substance of a lecture delivered by Dr. J. H. Gaddum "Chemical Transmission in the Central Nervous System", 741
University College of Wales: Symposium on "Climatic Factors and Agricultural Productivity", 438
University Grants Committee: Sir John Wolfenden appointed Chairman, 23
    Returns from Universities and University Colleges in receipt of Treasury Grants, Academic Year 1960–61. (Cmnd. 1855), 1, 24
University of Belfast: Appointments, 132
University of Birmingham: Dr. T. Alty appointed deputy principal, 952
    Appointments, 132, 1156
University of Bristol: Appointments, 1253
University of Cambridge: Summer school on "Electron Microscopy of Thin Crystals", 438
University of East Anglia: Dr J. A. Kitching appointed to the chair of biology, 1153
University of Glasgow: Third European Mycological Congress to be held in August–September 1963, 1054
University of Kansas: Library Series No. 15, *William Dampier*: *Seaman-Scientist*, 22
University of Keele: Grant from the Nuffield Foundation for the Establishment of a Statistical Research Unit in Sociology, 652
University of Leeds: Appointments, 132
    Dr. P. J. B. Clarricoats appointed Professor of Electronic Engineering, 952
University of Liverpool: Chair of Genetics, 20
University of London: Appointments, 132, 1156, 1253
    New Physics Building at Queen Mary College (Prof. G. O. Jones), 1142
University of Manchester: Appointments, 20
University of Nottingham: Appointments, 132
    Tenth Easter School in Agricultural Science, 236
University of Otago, New Zealand: Substance of an address delivered by Dr. I. W. Wark, "Scientific Research as a Career", 737
University of Saskatchewan, The Institute for Northern Studies: First Annual Report 1960–1961, 960
    Second Annual Report 1961–62, 960
University of Southampton: Formation of Institute of Sound and Vibration Engineering, 132
    Substance of the Ninth Fawley Foundation Lecture by Sir Julian Huxley, 8
University of Sussex: Third Annual Report, 652
Unmack, A., and S. L. Rowles: Constituents of Dental Calculus from Sheep, 486
Unusual Behaviour of a Mammalian Collagen in Deuterium Oxide (J. Bello and H. R. Bello), 77
Unusual Twinning in Graphite (J. M. Thomas, E. E. Glenda Hughes and B. R. Williams), 682
Upper Cretaceous of Central Europe (Dr. J. M. Hancock), 238
Upper Mantle Materials: Uranium and Thorium Abundances in Possible (Dr. J. F. Lovering and J. W. Morgan), 138
Ur, H., et *al.*: Charge-Transfer Complex Crystal Growth at a Solution–Solid Interface, 373
Uranium and Thorium Abundances in Possible Upper Mantle Materials (Dr. J. F. Lovering and J. W. Morgan), 138
Uranium and Thorium Carbides: Acid Leaching of (P. L. Pauson et *al.*), 1200
Uranium (VI)–Chromotropic Acid Chelate (S. K. Banerji and A. K. Dey), 1002
Urbański, T., and A. Czyżyk: Influence of 5-Bromosalicylhydroxamic Acid on Serum Cholesterol-level, 381
Urea Cycle in the Liver of the Rat: Effect of Carbon Tetrachloride Intoxication on the Activity of Enzymes of the (F. Rossi and Patricia McLean), 1207
Urea-Levels in Blood and Tissues of Hibernating and Non-Hibernating Hedgehogs (R. Kristoffersson), 402
Urease and Citrase of Pathogenic and Saprophytic Fungi (Dr. H. Seneca, P. Peer and R. Nally), 359
Ureter: Unequal Bilateral Sodium Excretion in Sheep with an Exteriorized (B. D. Stacy and A. H. Brook), 49
Urey, Prof. Harold C.: Cometary Collisions and Tektites, 228
Uricolytic Enzymes in Soil (Margaret Martin-Smith), 361
Urinary Acid Mucopolysaccharides: Heterogeneity of (W. R. Kelley et *al.*), 1204
Urinary Amino-acids on Phenylalanine–Tyrosine-supplemented Diets (M. J. Carver and R. Paska), 493
Urinary Salicylate Excretion Rate: Relationship of Plasma Salicylate Concentration to (Prof. E. Nelson and Prof. G. Levy), 1269
Urine: Fractionation of a Substance containing Hexosamine, isolated by Precipitation with Calcium Chloride from Normal (Z. Brada), 592
    Inactivation of Thrombin by Normal Human (H. A. Gaertner et *al.*), 188
Urine after Injection in Lateral Ventricle of the Brain of a Cat: Effect of Posterior Pituitary Polypeptides on the Flow of (B. S. Nashold, jun., et *al.*), 293
Urine and Adrenal Incubates of Patients with Arterial Hypertension: Isolation of a Polar Aldosterone-like Substance from the (H. E. Carr, jun., and I. Naukkarinen), 696

Urine of a Patient with a Carcinoid Tumour : Tryptamine in the Blood and (D. Eccleston *et al.*), 502
Urine of Intact Stilboestrol-treated Guinea Pigs : Sex Differences in the Pattern of Radio-iodine Excretion in the (A. Slebodziński), 801
Urist, M. R., *et al.* : Utilization of Proline during Healing of Fractures, 803
Urokinase to Bradykinin- and Plasminogen-induced Capillary Permeability: Antagonistic Action of (A. L. Copley and V. Tsuluca), 294
Use of *Cyclophosphamide* in an Attempt to modify the Canine Renal Homograft Response (G. B. Reams), 713
Use of Modified 'Bentone-34' for the Gas Chromatographic Separation of Aromatic Hydrocarbons (J. V. Mortimer and P. L. Gent), 789
Use of Spleen-slice Homografts in the Study of Graft-versus-Host Reactions (H. B. Wheeler, J. M. Corson, J. A. Coyne and G. J. Dammin), 712
Use of the Ninhydrin Reaction for Quantitative Estimation of Amino-Groups in Insoluble Specimens (P. A. Kendall), 1305
Use of Xenon Adsorption for Measurements of Surface Area (W. A. Cannon), 1000
Usher, P. D. : Radio-Transit Telescopes steerable in Azimuth, 170

PROVISIONS FOR UNIVERSITY EXPANSION IN BRITAIN

THE major pre-occupation of the general survey with which the University Grants Committee prepares its comparative statistics for 1960–61[*] is, as might have been forecast, finance. In the main, the Committee is content to present the facts rather than comment on the implications of the Government's refusal to accept the Committee's recommendations for the next quinquennium designed to provide places for some 150,000 students in four years time. Returns for existing universities indicated that they could increase their student numbers to 144,500 by 1966–67, dependent on the recruitment of staff and provision of adequate recurrent grants, and if the new universities, for the development of which the Committee had earmarked capital sums up to, and including, 1965, can provide 7,000 places by 1966–67 a total of about 151,000 should then be available, an increase of 36 per cent over 1961.

The Committee is satisfied that there is no shortage of applicants of the requisite ability, nor is it particularly disturbed at the rate of failures revealed by further inquiries on first-degree students. Of the 82·8 per cent admitted in October 1957 who obtained their first degree, 76·9 per cent did so in the normal period, and of the 14·2 per cent of 'failures', 11·8 per cent left for academic reasons and 0·1 per cent for disciplinary reasons. In medicine, dentistry and veterinary science, however, 29·9 per cent of the students required more than the normal time to achieve success.

Leaving for the moment the question of student numbers and quality with the rider that this evidence underlines all that the University Grants Committee emphasizes about the importance of academic staff of the highest quality, it should be noted that the steady rise in net expenditure on existing commitments itself limits the provision which the universities can make for expansion of the undergraduate population. Furthermore, the University Grants Committee has already earmarked sums totalling in the region of £2,000,000 by the end of the quinquennium to meet special needs in research and teaching, in the main at the Government's own request. The Committee recognizes that there is little money available in the new quinquennium for any other developments than those concerned with student expansion, and in the early years of that quinquennium the Treasury grants announced scarcely cover the increasing costs of existing commitments.

It is obvious that the University Grants Committee is relying on the indication in the debate in the House of Commons on April 5, 1962, that a fresh review of the universities' financial situation in two years time may lead to a further offer from the Government; however, the critical factor in expansion is not finance, at least not directly, but staff. It is this that gives such pertinence to the Committee's discussion of academic salaries, for obviously the ability to recruit a sufficiency of academic staff of high quality depends a good deal on the salaries offered. At the time of writing the report, the University Grants Committee was frankly concerned with the effects of the then suggested 3 per cent salary increase in the universities on the retention as well as on the recruitment of university staff. The Committee of Vice-Chancellors and Principals described this increase as entirely unrealistic and inadequate to enable universities to retain and recruit the academic staff required for the proposed expansion. However, in this context it remains to be seen how effective will prove the Government's present recommendations to the National Incomes Commission.

The University Grants Committee devoted considerable time during the year to the question of the ratio of academic staff to students, and it notes too that the increasing importance of research makes higher demands of staff time per student through the supervision involved. The present overall ratio, excluding Oxford and Cambridge, is estimated at 10·4, compared with 9·2 in 1954–55 and 11·7 in 1938–39; but it is pointed out that over the whole period the ratio in science and applied science has become worse: if staffing was in balance in 1938–39, these faculties were about 30–40 per cent understaffed in 1961–62, and a sample survey of academic posts vacant in June 1961 showed that 5·6 per cent of the posts were vacant. In the pure and applied sciences the figure was 6·5 per cent.

These figures, in fact, represent little more than the normal turnover in such posts, but at least they indicate the extent to which the universities have to compete with salary changes elsewhere in maintaining as well as recruiting staff. Moreover, although the Government's willingness to meet by supplementary grant the cost of academic salaries (about 44 per cent of the total) has made it possible to maintain the quinquennium system, this does nothing to cover the creation of new and higher posts or the reorganization that is often needed in anticipation as well as part of expansion. Furthermore, there have been increases of 98 per cent in national insurance, 37 per cent in pensions, 29·9 per cent in non-academic salaries and wages, 28 per cent in rates and taxes, and 24 per cent in the cost of books, periodicals and bindings between June 1956 and June 1961, the dates on which the universities framed their estimates for the 1957–62 and 1962–67 quinquenniums.

This represents an increase of some £4·7 million towards which the Government in 1959 made a supplementary grant of rather less than £1 million. The universities' expenditure on rates (about 2·2 per cent of the total in 1961–62) is indeed to be made the subject of earmarked grants during the coming quinquennium, in view of the changes made by the Rating and Valuation Act, 1961; this means that about 46 per cent of university income can now be augmented by supplementary grants to meet circumstances which are beyond university control. Nevertheless, the pressure remains particularly acute at precisely the point which is most critical for the expansion of the universities. Whatever may be possible in the way of providing new and less-expensive types of accommodation for students or making more effective use of existing accommodation and equipment, whether for teaching or research, the question of staff remains. Discount as we may the complaints that communication between staff and students is at present inadequate or non-existent, to raise it to the level of the past practice at present calls for some improvement in the ratio of staff to students. The expansion of postgraduate teaching as well as of research in itself calls for higher ratios, and the present evidence is that in many subjects the universities are already failing to retain their staff.

This question of student–staff relations is one of the most important points brought out by Prof. H. Butterfield in his Lindsay Memorial Lectures†. Universities, he maintains, ought primarily to be regarded as the arena in which occurs the electric contact between teacher and pupil. This should be the supreme object of the educational arrangements. It is the more important as the proportion increases of students who come from homes with no tradition of books or learning and who tend to regard the university as a mere production line. If arrangements so discourage this vital contact between teacher and student that the student never really experiences the university atmosphere at all, the university fails in its purpose, and this can result equally from the admission of too many undergraduates as from failure to provide the conditions of work or salary which attract and retain teachers of the requisite quality.

We are in danger, continues Prof. Butterfield, if we allow any pressure to train students for examination to lead us to overlook the urgent need to elicit the maximum intellectual power at every level. It is of the utmost importance for Britain as a whole—for her economic life, her intellectual development, the work of Government—that the universities should foster in their students imagination and flexibility of mind. The universities, moreover, have a creative work to perform both in handling young people and in the development of science, scholarship and thought, and it is at this point that Prof. Butterfield stresses the danger of allowing teaching and research to be divorced from one another. The place of research in the life of the university has become much more important in the past two decades, and he recognizes, too, that young men even in Oxford and Cambridge no longer have the same informal contacts with the dons, but he believes that it is far better to accept the existing tensions and heavy double programme of work than to admit the division between research and teaching which some have urged.

It is from this point of view that, in his second lecture, Prof. Butterfield discusses the academic profession. He emphasizes first the creative possibilities of teaching, the importance of the teachers in the progress of society and culture and the advantage that accrues when teachers perform their task in an atmosphere and mood of intellectual exhilaration. He is not uncritical of the present position and of some of the problems which arise in the administration or government of universities, but in this lecture he directs attention to what is commonly overlooked in discussions on academic salaries and university finance. It should be a first consideration of Government policy to promote just the conditions which he desiderates. Measures which are directed primarily at the expansion of student members to the detriment of those conditions are as unsound as they are wasteful.

Behind this, however, as he fully recognizes, lies the question of the relations between the university and society, and here again he has some wise words. With universities as with professional organizations generally, rights are correlative to responsibilities: academic autonomy is merely the requisite condition for fulfilling a university's responsibilities to society. There probably should always be a tension between universities and either society or Government, and it may be the duty of the university to maintain its side of the tension, if it is not to abdicate its responsibility for leadership. Prof. Butterfield believes that universities exist to serve society, but that it is a part of their service to conduct a search for truth which, if necessary, shall be independent of any immediate utilitarian end. He sees them as existing to produce good citizens, wise statesmen and able industrialists rather than first and foremost seeking to provide more dons and teachers.

Unless a university is able to perform these functions it will not render its most vital and characteristic service to the community, and Prof. Butterfield is well aware that some of the pressures for university expansion—not least the Government's own policy—could seriously impair that capacity. While, however, it will need a strong tradition and powerful professional organization to prevent universities from becoming mere factories for the production of examination candidates, Prof. Butterfield rests his main hope for the preservation of the academic ideal on the teachers themselves in contact with the young. The prime pre-occupation must be with that ideal, with maintenance of standards and the vindication of liberty, not with the development of particular branches of scholarship.

In his last lecture Prof. Butterfield refers again to the opportunities of the new universities, stressing in this context the extent to which the problems of the world are essentially humanist problems requiring insight and experience in respect of human personality, human issues and human relations. The notion of liberty of men and women in Britain, their democratic systems, their urbanities and tolerances and love of liberal-mindedness represent the late flowering of a humanist civilization which century after century has directed so much attention to men and problems of human relations. The transmission of these imponderables of tolerance and self-discipline is far more difficult than the transmission of science and technology, and in this transmission of our cultural heritage extra-curriculum activities play an important part. The preparation for responsibility in society, in fact, devolves more and more on such activities, and that once again indicates the vital importance of effective communication.

Until December 27, there had been no real indication that the Government appreciated the importance of this central issue which once again turns on the quality and the numbers of the academic staff. By putting first the expansion of the student population and failing to provide the resources which the universities themselves consider they need to deal effectively with that expansion, it is in danger of defeating its own purpose. Even if the universities are able to retain sufficient staff and increase the load on them, the most brilliant improvisation will scarcely ensure that more than a proportion of the students really receive a university education. If the Government is convinced that the nation can, in fact, not afford a public expenditure of more than £116 million in 1961–62 and £140 million in 1966–67, it would be sounder policy to consider diverting, for the time being, a larger proportion of the school-leavers to the colleges of technology and other institutions of higher education. Desirable as it may be to increase Britain's output of graduates, it is even more important that their quality should be maintained. It is obvious from the lively discussions already proceeding and from evidence tendered to the Robbins Committee that the efficiency of the universities could be improved in some respects and that there may be ways of reducing the cost per student. What is equally clear is that the financial pressure on the universities is already such as to raise serious concern as to their ability to deal adequately with their present responsibilities for teaching and research if the conditions that they are to offer their academic staff are not quickly improved.

---

† *The Universities and Education Today*. The Lindsay Memorial Lectures given at the University College of North Staffordshire, No. 2. By Prof. Herbert Butterfield. Pp. viii+110. (London: Routledge and Kegan Paul, 1961.) 12*s*. 6*d*.

That the Government has now decided to refer the question of university salaries to the National Incomes Committee shows that it has at last accepted the advice of the University Grants Committee as to the need for immediate increases in university salaries. The announcement on December 27 of an actual salary increase of £3·5 million a year from April 1, 1963, sufficient to provide an overall increase of 10 per cent, provides the universities with an important salary basis for recruitment. However, in the present circumstances, it is unlikely by itself to remove the existing dissatisfaction in view of the claims previously advanced by the Association of University Teachers, which has already protested to the chairman of the University Grants Committee.

INFORMATION U.S.S.R.

Information U.S.S.R.

An Authoritative Encyclopædia about the Union of Soviet Socialist Republics. Edited and Compiled by Robert Maxwell. Pp. xii + 982 (illustrated). (Oxford, London, New York and Paris: Pergamon Press, 1962.) £10 net.

THIS is far more than a book—and one that ought to be in every library worth the name throughout the length and breadth of English-speaking lands. The *Great Soviet Encyclopædia* is a gigantic work of reference which can bear comparison with comparable encyclopædias in any country, and what Mr. Robert Maxwell and the Pergamon Press have done is to translate into English Volume 50 of the *Soviet Encyclopædia*—the volume which deals with the Soviet Union itself. What therefore is presented to the English-speaking world is the Russian world as seen and described by its own leading experts and as presented to its own people. It occupies 762 large quarto pages in double column, or much more than a million words, and, as if that were not enough, there follow 150 pages of statistics—the "U.S.S.R. in Figures, 1960", which is translated directly from the Russian handbook with the same title. Two exhaustive indexes of names and topics occupy nearly a further hundred pages, and so complete a monumental tome of approximately a thousand pages.

Robert Maxwell is a remarkable young man—still under forty—of Czech origin, who speaks and reads fluently at least nine languages, including Russian. After a distinguished war career, underground and later commissioned and decorated in the field, he was with the British Foreign Office until in 1947 he set up the scientific publishing house, Pergamon Press, now one of the largest organizations of its kind in the world. Holding that knowledge is the key to better world understanding, he regards *Information U.S.S.R.* as the first of a series of reference books, each to be written by the leading experts of their own country, which will eventually cover the whole world.

Information U.S.S.R. has been produced with the cordial collaboration of the Government Scientific Publishing House which produces the *Soviet Encyclopædia*, and already it has been discussed in principle that comparable works, *Information Great Britain* and *Information U.S.A.*, might be published simultaneously in Russian and English. Mr. Maxwell is already alive to the major problem of encyclopædias—that they quickly get out of date, and he plans annual or periodic supplements to keep them up to date.

Such a project staggers the imagination by its immensity, but what the Pergamon Press has already achieved in a dozen years of life leads one to believe that if anyone can see it through to fruition, that person is Mr. Maxwell. So much is at stake in a world rent by 'cold wars' that surely the effort deserves the fullest support: let every reader of this notice for a start make certain that his institution secures its copy of *Information U.S.S.R.*

To review the contents is an impossible task. If one dips into those sections covering one's own fields of study one is struck by the excellence and smoothness of the translation. Russian names which are so frequently mangled in English are given their correct transliteration and diacritical marks; for example, what normally appears in English as the Tian Shan are given as Tyan'-Shan' and Lwow as L'vov. One may object to anticlinoriums, but where rises and falls in the surface of the Palæozoic platform are designated anticlines and synclines one presumes this is the usage of the original. There are full references to the original literature, the works being given in Roman lettering, so that as with place-names one has a standard transliteration. Good tests of the adequacy of translation are afforded by the sections on soils and vegetation. Both are well done and it would be a severe critic who found serious fault. It is recognized that 'takyr', 'solonets' and 'solonchak' are not to be translated, and one is introduced to 'takyrization' quite naturally. Throughout 's' is used in preference to 'z' (podsol, not podzol). We are also given permanently frozen subsoil (*merzlota*). It should be noted that throughout the numerous maps and diagrams in the text and folding maps have been translated with equal care.

Section 15, "Science and Scientific Institutions", occupies no less than 140 pages. Undoubtedly the impression one gets is that science is a monopoly of the Soviet Union and in the main of the Soviet régime; it is scarcely possible to find other than a Russian name mentioned. It is thus a record of Soviet scientific achievement as seen by themselves: the Western reader must be left to see where the whole fits into the world pattern. But this is what is given to the students in Russian universities and to the intelligent reading public: it is right that readers in English should see for themselves exactly what is being disseminated entirely without editorial comment or alteration. L. Dudley Stamp

A DRIFT BETWEEN CONTINENTS

Animal Geography

By Wilma George. Pp. vi + 142. (London, Melbourne and Toronto: Heinemann Educational Books, Ltd., 1962.) 21*s*.

BOOKS on zoogeography are too few, too specialized or too inaccessible for a welcome to be withheld for one that "provides an introduction to the study of the distribution of animals . . . for those who are starting zoology at school and for those whose knowledge has progressed further but who require a brief survey of the subject". This latest book, excellent in so many ways, could meet the needs of the second category of reader but might fail for the beginner since it demands almost specialist knowledge for easy reading or ready understanding.

Only the vertebrates are dealt with, and among these the mammals are used predominantly to illustrate the principles. The text is divided into four parts: "Present", "Past", "Past to Present", and "Islands". In the first, we are introduced to the use of maps and to the classification of mammals, down to families, and to the 'thumbnail' pictures of mammals used as symbols throughout the book. The six zoogeographical regions are then explained, the methods of dispersal as well as the barriers to it, the outlines of evolution in mammals, and the three theories on the probable distribution of the land-masses in the past. The fourth part is devoted to the interpretation of island faunas.

Its author has the unenviable task of trying to simplify a tangled field of knowledge in which explanations must be attempted although so many unknowns and variables need to be reconciled. There is a pleasing reluctance to be dogmatic, and a commendable readiness to keep the reader reminded continually that so much that is said on this subject is based on theory. The style is straightforward and the diagrams clear, indicating the author's pioneering in the use of economy of words linked with visual aids (obviously with "those who are starting zoology at school" in mind). It is with reluctance, therefore, that one ventures to direct attention to what may be shortcomings, but this may be of help in a future edition.

It was with some slight surprise that, on finishing the book, one turned back to the title-page to be reminded that the author is "Fellow and Tutor in Zoology . . . [at] Oxford", instead of at Harvard. There is something non-British (and highly commendably so) in the remark (p. 33) that ". . . Darwin and Wallace announced the theory of natural selection . . ." (Wallace is usually dismissed in a single line.) There is an American flavour in other respects also. Instead of the familiar Palæozoic and palæontology we have paleozoic and paleontology, and Cænozoic becomes cenozoic. The loss of the diphthong may be a matter of taste, but the dropping of the capitals impedes one's reading whenever it occurs, perhaps only because the eye is not used to it. It may be that with the increasing interchange of American and English editions the time is already here when uniformity should be sought in such matters or imposed by pioneers like Wilma George.

Even so, the use of conies for hyraxes, with no explanation at all, seems unjustified. The word originally referred to *Oryctolagus cuniculus*. It is true that we have corruptedly standardized the name for a young cony (that is, the rabbit) by applying it to adults as well, and admittedly the conies of the Bible refer to hyraxes. Yet even in the United States, where some authors tend to use it alone when they mean hyraxes, the best-informed mammalogists render it as hyraxes or 'conies'.

The otherwise commendable brevity in style of this book can at times go too far. It is, for example, doubtful whether many Fellows of the Royal Society even, much less beginners in schools, would know offhand what a degu is, or a blesmol, even if they knew that Rhyzomyidae (p. 28) should be Rhizomyidae ; and a "Dalliid blackfish" is, to say the least, unfamiliar and should be given a brief amplification, unless the aim is to compel the beginner zoologist to go rooting around among specialist books or the best encyclopædias. Maurice Burton

ORGANIC MICROANALYSIS

Methods of Organic Elemental Microanalysis

By G. Ingram. Pp. xvi + 511. (London: Chapman and Hall, Ltd., 1962.) 75s. net.

The periodical literature on organic microanalysis has now reached vast proportions, and the newcomer in this field—and, indeed, the moderately experienced technical analyst—needs some sort of 'filter' which will offer to him the critically assessed best of what have been proposed in the way of methods. To act as such a 'filter' has been the aim of Mr. Ingram, and he has achieved this very well indeed. Previous text-books on organic elementary analysis have tended to be the products of 'schools'—where sometimes one might suspect a certain amount of special pleading. Mr. Ingram is not a member of any school or, in a sense, perhaps he is his own school. Out of a severely critical approach and a vast experience he has presented the best of the published methods, and has argued his choice competently.

He has elected to take a quite unusually wide interpretation of 'organic elements'. Instead of restricting himself to the usual ten, or at most about sixteen elements usually dealt with under this heading, he has recognized that more than fifty elements may be required to be determined in organic materials; he has widened his net accordingly.

He has also taken note of the remarkable advances in the ultra-micro range in the past few years, and has included a section dealing with the elementary analysis of samples of the order of 50 μg.

Mr. Ingram comments on one interesting anomaly: that although the techniques of organic elementary analysis have altered vastly in the fifty years that have passed since they were first devised by Fritz Pregl, the fundamental basis for the determination of some of the elements, for example, carbon and hydrogen, is still that evolved more than a hundred years ago. He suggests, with some justification, that more thought could be given to this by organic microanalysts than has been done in the past.

This book is a valuable contribution to the literature. It makes one hope that the author, in due time, may turn his attention to the field which here he has deliberately excluded—organic functional analysis.

C. L. Wilson

BIOLOGY IN AMERICAN HIGH SCHOOLS

High School Biology

Revised edition. American Institute of Biological Sciences. Biological Sciences Curriculum Study Committee on Innovation in Laboratory Instruction for Experimental Use During the School Year 1961/62.

A. (1) Blue Version. (2) Yellow Version. (3) Green Version (each version consisting of Text, in three parts, The Laboratory, in three parts, and The Laboratory (Teachers') Guide, in three parts).

B. Laboratory Blocks of : (1) Microbes : Their Growth, Nutrition and Interaction, by Alfred S. Sussman ; (2) Animal Growth and Development, by Florence Moog ; (3) The Ecology of Land Plants and Animals, by Edwin A. Philips; (4) Interdependence of Structure and Function, by A. Glenn Richards ; (5) Animal Behavior, by Harper Follansbee ; (6) Plant Growth and Development, by Addison E. Lee ; (7) Regulation in Plants by Hormones, by William P. Jacobs and Clifford E. LaMotte.

C. The Teacher's Handbook (all-Text Version, parts 1, 2 and 3).

D. Biological Investigations for Secondary School Students, in two parts.

(The series are not in fact classified A, B, C . . . 1. 2, 3; this is done here purely for simplicity.)

(Washington, D.C. : American Institute of Biological Sciences, 1961 and 1962.)

Curriculum reform in American education has been carried out on a truly large scale in recent years at a cost of four million dollars furnished by the National Science Foundation. Starting in 1959, seventy teachers in schools and universities, together with other scientists, set about a comprehensive re-orientation of school biology. A first writing conference produced three different types of high school courses which were used in 1960–61 by 118 teachers and their 14,000 pupils in seventeen States. A second writing conference produced revised versions of the three courses which have been used in 1961–62 by 541 teachers and their 56,000 pupils in thirty-five States, while a final version is to be made available on the American market in September, 1963, following a third definitive writing conference. It is the second revision which is the subject of this review.

To appreciate the significance of this remarkable *tour de force* both for British and American education it is essential to understand routes by which British school biology has reached its present scope and acquired its present character. At least 80,000 boys and girls enter for biology each year at the Ordinary Level of the General Certificate of Education in England and Wales, and thus exceed the entries for any other single science by some 18,000; and three-quarters of these entrants are girls. The ratio of degrees awarded each year in biological subjects to passes each year at Advanced Level and Ordinary Level is approximately 1 to 7·5 and 1 to 94 respectively. Thus the bulk of school biology is not concerned with either entry into university or university type of work, a fact which has to be balanced against the currently fashionable idea that mathematics, physics and chemistry is the only proper intellectual diet for science sixth formers. Another striking fact is the extent to which Advanced Level examination questions are predominanty descriptive and out of phase with contemporary biological thought and emphasis.

In this situation the moves afoot to re-align school biology are nationally important, vigorous and extensive as a study of the publications of the past three or four years shows well. Britain's 'gadgetry' is excellent, several stimulating schemes for reform are in existence, and nationally important bodies provide several types of facilities to teachers. The needs are to raise the standard of intellectual rigour of biology by modernization, shift of emphasis and reduction of study of too much dead material. In the long run new forms of training for teachers will be necessary, a far closer co-operation between school and university called for and a big increase in the supply of laboratory technicians in the schools at a far greater cost than now. Yet no real change is possible until the examination boards alter their policies and syllabuses and type of examination.

The American problem is essentially like Britain's, and has been stressed in urgency by reaction in the 1950's to Soviet performances. This is why the publication under review, running as it does into thirty-eight volumes, is bound to have a world-wide impact.

The American panels first set out nine basic biological concepts all of current research interest:

Evolution, diversity of animal and plant life in relation to unity of phylogenetical patterns, genetic continuity, relation of organism to environment, relation of structure to function, biological roots of behaviour, homoeostasis, and science as inquiry. Intellectual history of biological concepts is woven into the treatment.

From this three courses were prepared, each comprising three text-books to cover a yearly course and containing a greater volume of material than the pupil is expected to remember. Each course also has three laboratory manuals, one for each text-book and forming the main course to which the reading in the texts is a background. There are also three teacher's handbooks with each course.

The 'Green' course starts with ecology and relationships and works up to biochemistry; the 'Blue' course emphasizes biochemistry and works by stages towards ecology, while the 'Yellow' course begins with cytology and works in two directions from it, one towards biochemistry and the other towards ecology via various levels like physiology and systematic biology. 70 per cent of the matter is common to all three courses. The level of presentation is directed at the 16–18-year-old pupil.

In assessing the extent to which these works achieve their aims it is necessary to realize the completeness and the revivifying effects of the break with traditional methods and thoughts. The practical work impels the course on its way and is not didactically presented but is introduced as a form of research. The ingenuity of the practical methods is excellent. In addition, supporting volumes set up two new themes. One is the laboratory block by which single or small teams of pupils are given a stretch of six weeks full-time laboratory work. "During the next six weeks we want you to work like a scientist" is the opening sentence of the block. The second new theme is the provision of volumes written by research biologists stating 150 research problems within the capacity of the pupils and to which the answers are as yet unknown. Throughout, the style of writing is exciting and I myself have tested the effects of it on my own pupils and am convinced of its adequacy for its avowed purpose. The quality of the illustrations is not high; but it has to be remembered that one is seeing an interim version, not a final commercial production.

The success of this splendid experiment will be measured in proportion to its effectiveness in stimulating and shifting opinion outside the United States. [See also *Nature*, 194, 242; 1962.] L. M. J. Kramer

PHYSICO-CHEMICAL TECHNIQUES IN PHYSIOLOGY

Physical Techniques in Biological Research

Edited by William L. Nastuk. Vol. 4: Special Methods. Pp. xiii+410. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1962.) 13 dollars.

The previous volumes of this series were concerned with optical techniques (1955), physico-chemical techniques (1956), physical methods of observation of cells and tissues (1956).

Now, after an interval of six years, a new volume with a new editor, dealing with "Special Methods", has appeared. This is concerned with various specialized physico-chemical techniques with applications in physiology. S. Chien and M. I. Gregersen have written a comprehensive monograph on the determination of the volumes of body fluids which will be invaluable to all who are concerned with this. E. M. Renkin writes on the techniques of vascular perfusion—a method which has extensive uses in studying the functions of different tissues or organs. A more physico-chemical parameter, which is of considerable interest in connexion with tissue metabolism and has importance in radiotherapy, is the oxygen tension. P. W. Davies discusses the use of oxygen cathodes of various types in these determinations. It appears that successful determinations can be made by using the ability of oxygen to depolarize cathodes, the extent of depolarization depending on the diffusion of oxygen in the medium. A. B. Otis describes physical techniques used in the examination of respiration—mainly involving the analysis of the gases involved. M. Margoshes describes recent studies of flame photometry—a method of determining certain metals which has been greatly refined by the more exact control of temperature. Finally, W. T. Fry and F. Dunn contribute a lengthy monograph on ultrasound, which deals very comprehensively with the methods of producing ultrasound and its physical properties. This section contains much more information than most biological users of ultrasounds could be expected to require. Certain biological applications are rather briefly described.

The articles differ considerably in their comprehensiveness, and in several cases go much beyond the declared aim of the series—to provide critical and useful information for graduate students and also investigators needing to use a particular type of technique.

Two more volumes of this useful series are promised, to deal mainly with certain electrophysiological techniques and types of apparatus. It is to be hoped that these will not be delayed too long. J. A. V. Butler

INTERNATIONAL GEOPHYSICAL CALENDAR 1963

THE International Geophysical Calendar designates selected days and intervals for special attention for geophysical experiments and analysis, and is thus a framework for world-wide co-ordination. The Calendar serves mainly the branches of geophysics dealing with the Earth's atmosphere in which many phenomena vary significantly during the course of a year. In some experiments, such as the routine recording of variations of the Earth's magnetic field, the observing and analysis programmes at observatories are normally carried out at a uniform level throughout the year; in these cases the Calendar is not needed. However, in many other experiments (for example, rocket experiments), it is not practical or meaningful to carry out the same programme on each and every day. Here the Calendar can provide a useful mechanism for co-ordination; experimenters will know that their colleagues in other countries, in other laboratories, and in other disciplines will tend also to carry out experiments on the days or intervals marked on the Calendar. In this way, results of experiments may later be more easily and usefully compared.

In some scientific fields, international scientific organizations have made specific recommendations for programmes to be done on days or intervals marked on the Calendar. In others, the arrangements are informal or self-evident. Some examples are given here.

Regular World Days (*RWD*)

These are intended for observations or analyses or special experiments which as a practical matter can be performed for only about 10 per cent of days and should be in groups of three consecutive days and spaced throughout the year. One day of each group of three is designated as the *RWD* with highest priority and may be used for similar work which can be undertaken for only one day each month. Examples of suitable programmes in ionospheric physics are: oblique incidence pulse transmission and reception; absorption measurement by pulse reflexion technique; extended observing schedule for whistlers and very-low-frequency emissions; analysis of vertical sounding ionograms by f-plot, h'-plot, etc.; hourly reduction from ionograms of F-region true height parameters hc and qc. It is recommended that exchange of copies of original ionograms in ionospheric vertical sounding work be made for the *RWD* with highest priority.

World Geophysical Intervals (*WGI*)

These are intended for experiments which for practical reasons cannot be carried on continuously, but for which statistics of seasonal variations are especially needed. The choice of intervals has been heavily influenced by the needs of the meteorology discipline. The intervals in 1963 are placed about a month after the equinoxes and solstices which are times of marked seasonal change in certain upper-air meteorological phenomena. The co-ordinated international programmes for meteorology call for extra effort in synoptic rocket sounding and balloon sounding during the *WGI*. Other programmes such as ionospheric drift and high-atmosphere wind measurements are other examples of suitable programmes for such intervals.

Other Special Days

Other special days marked on the Calendars include rocket-winds days, the days of solar eclipses, and days of unusual meteor shower activity. The *rocket-winds* days (February 24, 25, 26) have been selected by the Committee on Space Research (here referred to as COSPAR) for a series of simultaneous rocket measurements of winds in the lower ionosphere (up to about 200 km) by techniques such as grenades, sodium clouds and visible grenade glows. COSPAR further recommends that simultaneous ground-based measurements by radio methods also be made on these dates. The solar eclipses (January 25, July 20, 1963; January 14, 1964) are occasions when special programmes may be expected to be carried out in appropriate parts of the world to study the Sun and any eclipse effects on the Earth-atmosphere. The geomagnetism discipline has directed special attention to these eclipses. Ionospheric stations customarily increase their observing programmes even if the magnitude of eclipse at their location is small. Many solar activity observatories take extra observations and issue specially detailed reports to assist the interpretation of the geophysical effects. The days with unusual meteor shower activity include some of the important visual meteor showers and also unusual showers observable mainly by radio and radar techniques. Attention is directed to these days in case ionization produced by meteors may account for unusual effects in other geophysical experiments. The annual World Meteorological Day, selected by the World Meteorological Organization (WMO) as March 23 (not marked on the Calendar), was first celebrated in 1961. Its purpose is to make the services which national meteorological services can render to the various branches of economic development, as well as the activities of WMO better known and appreciated by the public of all countries.

World Days for the International Years of the Quiet Sun, 1964–65 (IQSY)

This present Calendar also shows January 1964, which is the first month of IQSY. This month therefore shows a pattern of world days which is somewhat different from 1963, but which will be followed in the International Geophysical Calendars for the IQSY period. The Regular Meteorological Days are each Wednesday (U.T.), on which it is recommended that particular efforts be made to obtain the maximum quantity of data, including rocket ascents and ozone radiation sonde ascents, as well as maximum altitude balloon ascents at 0000 and 1200 U.T. The World Geophysical Intervals for IQSY have been extended to cover 14 days.

Special Intervals not appearing on Calendar

Periods of great magnetic, auroral and ionospheric disturbance are also of considerable geophysical interest. World-wide co-ordination of observation is especially useful for stations not near the auroral zones, that is, places where the beginning of a major disturbance may not be immediately apparent from local observations. Notices of the Geophysical Alerts and Special World Intervals (*SWI*) are distributed by telegram or radio broadcast on a current basis by the solar-geophysical Regional Warning Centres of the *IUWDS*, the telegraphic addresses of which are as follows:

AGIWARN WASHINGTON (U.S.A.); DENPA KOKUBUNJI (Japan); NIZMIR MOSCOW (U.S.S.R.); IONOSPHARE DARMSTADT (G.F.R.) or GENTELABO PARIS (France) or AGI NEDERHORSTDENBERG (Netherlands). The meteorological telecommunications network co-ordinated by WMO carries such information once daily soon after 1600 U.T. Many geophysical stations increase their programmes or carry on special experiments during disturbed periods. Prompt notification of immediately significant geophysi-

cal observations and of major solar flare events which have important and sometimes long lasting geophysical effects, are also undertaken through the Regional Warning Centres.

The International Ursigram and World Days Service (*IUWDS*)

This is a permanent service of the International Scientific Radio Union (URSI) adhering to the Federation of Astronomical and Geophysical Services of the International Council of Scientific Unions (ICSU). This Calendar has been drawn up by A. H. Shapley and J. V. Lincoln in consultation with interested ICSU unions and committees, and representatives of the WMO. A fuller description of such Calendars has appeared in the *URSI Information Bulletin* and various widely available scientific publications. Further copies of the Calendar can be obtained from the Secretary-General, URSI, 7 Place Danco, Brussels, 18.

EDUCATION AND THE HUMANIST REVOLUTION*

By SIR JULIAN HUXLEY, F.R.S.

MANY people have made pronouncements about education: T. H. Huxley drew a memorable picture of a liberally educated man, and Dorothy Parker has maliciously described it as "casting sham pearls before real swine". But I want to define education as a social process. I see education as an organ of man in society, whose basic function is to ensure the continuity and further advance of the evolutionary process on Earth by the transmission and transformation of tradition.

To look at education in the perspective of evolution shakes us out of over-preoccupation with our immediate difficulties. It provides a corrective to the tendency of our neotechnic industrial civilization to think in terms of quantity rather than quality, and it gives new dignity and importance to the whole educational process.

Education helps to transmit experience and its results across the gap between generations. There are three stages of its evolution. In the first, transmission bridges only one generation-gap, as in carnivores like fox or lion, where the young animal, after a period of self-education by play, learns to hunt by accompanying its parents.

The second is marked by the beginnings of tradition, a set of social habits which endures through a number of generations. The most striking example is the Japanese monkey. Here each social group has its own traditional food-habits, but these are occasionally modified by adventurous innovations, which take two or three years to spread through the little community. This is a big advance, but it involves no real educational system.

The third, found only in man, is that of cumulative tradition, based on conceptual thought and communicated mainly by artificial symbols that must be learnt. As the tradition grows more complex and the system of communication more elaborate, organized education becomes a necessary part of the machinery for their transmission.

Cumulative tradition provides man with a second mechanism of inheritance and evolution superimposed on the primary genetic-evolutionary mechanism of his chromosomes, and often overriding it. This has pushed man across a critical threshold, from the biological to the psychosocial phase of the universal evolutionary process. In this new phase, evolution is manifested primarily and most strikingly in cultural change, only secondarily in change in genetic constitution.

Not only is cultural evolution much faster than biological: it also shows acceleration. In the lower palaeolithic a major cultural change took perhaps 100,000 years; in early civilization a few hundred; and now barely a decade—with all sorts of implications for education.

Yet, in spite of all his achievements, we must remember that man is an extremely recent phenomenon. He cannot be much more than a million years old, and that, in the perspective of life's evolution, is a bare half-minute out of a twenty-four-hour day; while the whole of civilization is compressed within one tick of the cosmic clock. What is more, he is sadly incomplete, an unfinished type, needing a great deal of improvement before he can do his evolutionary job properly. Human individuals, too, are obviously unfinished when first thrust into the world, and need a great deal of improvement before they can qualify as satisfactory social beings: and their improvement as individuals, as well as the eventual improvement of man as a type, depends largely on the improvement of education.

Improvement during biological evolution is manifested in the improved construction, working, and behaviour of animals and plants. As Darwin pointed out, it is the inevitable result of the blind and non-purposeful agency of natural selection, operating via the genetic mechanism of transmission and variation—the gene-complex.

Improvement during human evolution, on the other hand, is manifested in the organization, working and achievements of human societies and cultures. It is primarily the result of the collective action of psychological and social forces, operating via the psychosocial mechanisms of transmission and transformation, of course, including cumulative tradition.

We are only beginning the detailed exploration of the agencies of psychosocial evolution, but some important points are emerging. First, it is the general idea-system, the pattern of knowledge and belief, which essentially characterizes human cultures, and indeed is the prime determiner of their social organization, their material sub-structure, and their achievements.

Secondly, everything in human history which deserves the title of advance or progress, every improvement or hope of improvement of the human lot and man's hard destiny, has sprung from the discovery and dissemination of new knowledge and new ideas. But new ideas, and the knowledge of which they are the vehicles, must operate within the contemporary idea-system, and will also modify it. Education should help in ensuring that they do so effectively.

Major advance in evolution takes place in a series of steps, by a succession of dominant types, each new one with an improved organization, while the older types persist in an inferior position and in reduced numbers. During biological evolution, what is improved is bodily organization. But in human evolution, what is improved is psychosocial organization—the organization of knowledge, ideas and beliefs and the cultures and social systems related to them. The industrial national type of organization is higher than the literate barbaric, that in turn higher than the illiterate tribal type. Magic, myth, monotheism, scholasticism, science succeed and replace each other as dominant patterns of human thought; though here, too, the older organizations persist in a subordinate position.

---

* Substance of the Ninth Fawley Foundation Lecture delivered at the University of Southampton on November 27.

The knowledge explosion of the past hundred years has given us a new vision of human destiny—of the world, of man, and of man's place and role in the world. It is evolutionary and monistic, showing us all reality as a self-transforming continuous process, with no dualistic cleavage between soul and body, matter and mind, life and not-life, natural and supernatural. All phenomena, from worms to women, from radiation to religion, are natural.

It leads inevitably to a new dominant organization of thought and belief, and, after centuries of ideological fragmentation, to a new and comprehensive idea-system, which I call 'evolutionary humanism'.

Its upshot is clear. Man is not merely the latest dominant type produced by evolution, but its sole active agent on Earth. He is responsible for the future of the evolutionary process on this planet. Whatever he does, he will affect it. He must try to understand it and its mechanisms, and to steer it in the right direction.

In carrying out this operation, he must not sit back and expect supernatural aid. Its overriding aim must be defined in positive terms, like fulfilment and achievement —greater fulfilment (and less frustration and misery) for more human individuals, interlocking with fuller achievement (and less muddle and failure) by more human societies. This must be secured by a fuller realization of human possibilities.

To realize this aim man must learn to live in harmonious symbiosis with his planetary environment—a responsible partner instead of an irresponsible exploiter. He must abandon the heuristic idea of conquering Nature; he must co-operate and conserve.

If this view of our destiny is correct, clearly our educational system must come to terms with it.

Most educational systems are highly change-resistant because they are controlled by dogmatic religious or State organizations, because they are linked with the established social order, or just because of inherent conservatism. But our new system must itself be evolutionary, not change-resistant but change-promoting; it must transform as well as transmit. In part, this can be achieved by making girls and boys understand the moral duty of helping and guiding the evolutionary process in a desirable direction. But something more practical is also needed. If our aim be greater fulfilment, the next step in psychosocial evolution must be from the Welfare State towards a 'Fulfilment Society'. A humanist educational system will put the idea of a fulfilment society before children, and will provide them with opportunities for actual personal fulfilment—through knowledge (I remember Bertrand Russell once exclaiming: "How nice it is to *know* things !"); through disciplined adventure; through expeditions and travel; through painting and acting and making music; through beauty; through study projects and discussions; through responsible participation in group activities. It will have a curriculum of experience as well as a curriculum of subjects.

In adapting our old educational system to our new vision, much cargo will have to be jettisoned—once-noble but now mouldering myths, shiny but useless aphorisms, Utopian but unfounded speculations, nasty projections of our prejudices and repressions.

Thus, man was not created in his present form a few thousand years ago. Mankind is not descended from a single couple. Children are not born with a load of original sin derived from a "Fall", nor with a *tabula rasa* of a mind. There never was a Golden Age, nor a Noble Savage. There are no pure races, nor any Superior or Master Races. There are no Absolutes of Truth or Virtue, only possibilities of greater knowledge and fuller perfection.

On the contrary, mankind originated from a population of ancestral anthropoids about a million years ago. His subsequent evolution has been marked by the increasing complexity and improvement of his material, social and psychological organization, but also by the increasing magnitude of his crimes and follies. Human children are not a set of uniform learning machines, but highly complex and varied psychosocial organisms engaged on the difficult attempt of developing into satisfied and satisfactory human beings.

Education has to cope simultaneously with several distinct problems—the imparting of knowledge; the learning of skills and social habits; the transmission of traditions and beliefs; the formation of character and personality; and the crucial passage from childhood to adult life.

In tribal societies, children gain the knowledge they need by imitating the adults and participating in their activities. Punishment is rare. Their theoretical instruction, in tribal myth, morality and forms of adult behaviour is imparted by selected elders, usually with the aid of esoteric ceremonies and painful ordeals. There is no examination to test their knowledge, only an ordeal to prove their adulthood; no certificate to frame and cherish, only the fact of their acceptance as full tribal members.

We still inflict painful ordeals on our children, in the shape of a whole series of examinations; we still celebrate their successful survival of these ordeals by ceremonial activities, most elaborately by the solemn pomp of university commencements and degree days. Most psychiatrists will agree that one reason for the stiffness of examinations is psychological—the subconscious desire of the adult to revenge himself for past ordeals by subjecting the young to similar trials; and assuredly the gorgeous robes of the academic procession are worn not only to impress the community gathered for the occasion but also as a permitted outlet for donnish egos. Yet it is still true that a tribal boy's education may be a better preparation for life in a tribal society than is ours for life in our vaunted technological society.

Education must come to terms with humanism over its curriculum, over its relations with society, and over its methods of fostering the development of personality.

As regards curriculum, the solution is, in principle, simple. The advance of knowledge has at last given us a unitary picture of phenomenal reality: the curriculum must reflect this unity and itself become unified instead of consisting of a number of unrelated fragments called 'subjects'.

Simple in principle, but not so simple in practice ! The first difficulty is quantitative—the mere bulk of knowledge is too great. However, the prime function of education is not to impart the maximum amount of factual information, but to provide comprehension: and for this we need what we can broadly call 'ideas', together with the necessary modicum of facts.

Some ideas are better than others—they can handle more apparently disparate phenomena, bridge larger gaps, simplify greater diversity. Thus the single idea that the planets move around the Sun in ellipses, at one stroke simplified for us the whole working of the solar system.

Evolution is the most powerful and the most comprehensive idea that man has ever had. It helps us to understand our own nature, and our relations with the rest of Nature. It shows us the major trends of evolution in the past and indicates a direction for the future. It gives us a new sense of excitement and wonder, a new view of our relations with our planetary habitat and its resources, a new perspective in time, and a new sense of universal interrelatedness. We are made of the same matter, we operate by the same energy as the rest of the cosmos; we maintain and reproduce ourselves by the same mechanisms as the rest of life, unique only in having reached the psychosocial stage.

Thus the evolutionary idea must provide the main unifying approach for a humanist educational system, and evolutionary biology should become a central or key subject in its curriculum. Another unifying idea of great importance is the ecological. Ecology is scientific natural history: the science of relations, between organisms and their environment, and of organisms with each other.

It deals with the dynamic balance of Nature. Its central concept is the ecological community—an assemblage of different types of organism, inter-adjusted to give optimum utilization of the resources of the habitat. If the balanced pattern of relations is interfered with, the whole habitat may be damaged, together with the whole community inhabiting it.

From earliest times, man has been interfering ignorantly with more and more natural habitats and has exploited their resources more and more pitilessly. He has converted vast areas of once-fertile land into arid semi-deserts. Now that his exploding population is subjecting more areas to more technologically efficient exploitation, he is in danger of becoming the cancer of the planet instead of its guide.

In the educational systems of under-developed territories, children should be introduced to science by the biological way of ecology and physiology and their applications in conservation and health, not by way of physics and chemistry and their applications in technology and industry; and in all countries, ecology is essential as a basis for good land-use and productive development.

Man lives in a triple tier of environments—material, social and psychological. Ecology in the customary sense deals with man's relations with the forces and resources of external nature. Social ecology deals with man's social problems, within and between human societies. Psychological ecology deals with man's relations with the forces and resources of his inner nature, and the environment of ideas and beliefs with which he has surrounded himself.

How should our evolutionary-humanist approach take effect in education? We must end the fragmentation of the present system. Education must be comprehensive, reflecting all aspects of life; it must have a unitary pattern, reflecting the unity of knowledge and the wholeness of experience; and it must give growing minds a coherent picture of Nature and themselves.

For this, we need an integrated curriculum, in which separate subjects can link up with each other—physiology with chemistry and heredity, ecology with geography, soil science with agriculture and meteorology: reproduction leads on to biological evolution, evolution links back with geology and cosmology, and on to archaeology and human history: history links up with economics and social studies. Art and architecture, law and morality, science and technology are best treated as functions of evolving social man: they too evolve, and accordingly profit by being treated historically, not merely as separate packages of facts and principles.

Just how to plan and introduce such a curriculum is a matter for the educational profession. It will not be easy, in face of the competitive claims of traditional subjects and established departments, and of the portentous growth of factual knowledge and theoretical scaffolding. It will mean scrapping a great deal of dead wood and dead weight, and some sacrifice of specialists' *amour propre*. But I am sure that it can be done.

There are already sporadic beginnings. Medicine is throwing overboard a mass of unnecessary anatomical and other detail: universities are introducing courses of general studies: sixth forms are taking steps to correct earlier over-specialization. The American Institute of Biological Sciences has worked out a remarkable integrated curriculum for high-school biology, complete with new text-books, new prospects, new laboratory and field methods [see p. 4 of this issue]; and the Gulbenkian Foundation is following suit in Great Britain. But these are isolated sporadic measures. The task will only reach a satisfactory conclusion when we realize that, here as elsewhere, unity brings strength: in a unified curriculum, separate subjects need not compete for prestige and place but can reinforce each other.

This could give a new dynamic to the educational process. Children have a natural interest and curiosity; they want to know about this strange world, about human life and how to live it, to find out what it all means. If their education helps them in this instead of setting up a number of hurdles in their way, they will enjoy it, and will become willing co-operators instead of reluctant or obstructive victims. From being merely a preparation for a job or a career, education could become an integral part of life, an instrument of social evolution.

A humanist education should also help children to realize their capacities and to develop into well-integrated personalities. For this, besides the integration of subjects, we need an integration of activities. The educational system must set itself, not merely to by-pass frustration and overcome apathy, but also to provide opportunities—for active living, for satisfying achievement, for feeling significant.

This again will not be easy. Apart from difficulties of staff and facilities, and of linking school life, home life and social life, there is the difficulty of time. Once more, however, it not only can but must be done.

Here again, unification can lead to mutual reinforcement. So-called extra-curricular activities can be made to serve curricular ends, and vice versa. Children have a natural desire to achieve, to exercise their capacities, to count for something in life. If they find that their education helps them in this instead of treating them as temporary inmates to be dealt with by a combination of bribes and penalties, they will become willing participants.

Then the educator must be reminded that the mind-bodies he has to deal with are extremely diverse—they exhibit a high degree of variance, both genetic and non-genetic.

Unfortunately, ideological warfare between the environmentalists and the hereditarians is still rampant in the social sciences. The biologist must point out that their dispute is as silly as that between Bigendians and Little-endians in *Gulliver's Travels*. Neither environment nor heredity is the more important. Both are necessary: all characters of all organisms are the result of their joint effect—though the share of either in the combined operation may differ greatly. Thus the share of genetic determination is high in mammalian hair- and eye-colour, in human colour-blindness and various forms of mental defect, while that of environmental modification is high in size of flowering plants, or health and physique in human beings.

If a diversified population is made genetically uniform, as when man makes pure strains of dogs or wheat, more and more of its visible variation will be modificational, due to differences in environment. Conversely, if its environment is made uniform, as when an unselected strain of plants is grown in controlled conditions, more and more of its visible variation will be genetic in origin.

A surprising recent modificational change in man is the trend towards earlier maturity, which has been going on in Western countries for more than a century. The onset of puberty has been advanced by some four months every decade, from above seventeen in 1850 to about thirteen to-day. This is correlated with an acceleration of growth: during every decade of the past seventy years, Western adolescents have become bigger by about an inch in height and four pounds in weight. Whatever its cause, this trend has had various interesting consequences. Boys' schools are faced with a shortage of trebles for their choirs; and an average boy of fifteen is quite likely to be bigger than his woman teacher, and is fairly certain to have stronger sexual urges: while the average girl of fifteen is now psycho-physiologically a woman. The adolescent crisis has been shifted to an earlier age: our educational systems must adjust themselves to this fact.

Then there are various kinds of genetic difference for education to cope with. There are large quantitative differences in general intelligence, and also in the rate of mental development, notably between rapid developers and slow maturers: clearly the educational system must take account of such facts.

There are also qualitative differences in what I may call the psychometabolism of children—the way their minds handle the raw materials of experience, notably between visualizers, auditory types, concrete manipulators, and abstract verbalizers. The traditional verbal type of education is not very good for visualizers or manipulators.

There are genetic differences in creativity and in the capacity for absorbing and regurgitating academic knowledge: the two are not by any means always strongly correlated—indeed, a recent American study has come out with the suggestion that the U.S. educational system may actually be eliminating some of the best creative talent.

Moreover, there are psychosomatic differences, of body-build and temperament. We cannot expect that a skinny ectomorph will react to the educational process in the same way as a comfortable endomorph with double the ratio of guts to muscle and a radically different pattern of hormones in his bloodstream.

In this field, as elsewhere, the abnormal may shed light on the normal. Let me give two examples. Myopia—severe short-sightedness—is a genetic abnormality found in more than one per cent of children. It was probably of selective value during those stages of man's history when fine craftsmanship was needed and craftsmen were kept out of the fighting; but in the modern world it can be a severe handicap. However, the modern world has found a way to circumvent the genetic handicap, by correcting the defect with spectacles.

My second example concerns schizophrenia. This disordered condition of mind, which all too often leads to certifiable insanity, affects nearly one in every ten of all human beings. It almost certainly has a genetic basis and is due to a metabolic error which produces an abnormal chemical compound related to adrenaline. This interferes with the working of the brain's mechanisms for building up the chaos of our sensations into an orderly system of perceptions.

The schizoprone child begins to manifest overt schizophrenia when the disorderliness of his perceptual world throws him thoroughly out of gear with the ordered 'normal' world of his fellows. This usually happens during the adolescent crisis. Psychiatrists are busy devising chemical tests for the schizophrenia-provoking compound in the blood and urine and psychological tests for its effects on perception. These could be carried out in school: and then the schizoprones could be given treatment to correct their defect. This possibility, of helping to lift some of the heavy burden of schizophrenia from the shoulders of humanity, is a notable challenge to the educational profession.

The general challenge of human diversity remains. Man is the most variable of all organisms—anatomically and physiologically, intellectually and temperamentally. Furthermore, a large degree of diversity is a source of strength to human societies, especially to high civilizations.

It would be a good thing if the numbers of the too abnormal and the defective could be reduced, those of the more intelligent and more gifted increased; and perhaps one day eugenics will get busy on this. Meanwhile, the problem is how to utilize the existing diversity to the best advantage.

Prof. Roger Williams has proposed "Free but Unequal" as the motto of a modern society. Freedom in inequality is a good basis for an educational system to work on: but as a goal for it to work towards, I would suggest "Varied Excellence".

Educationists must struggle against conformism and resist the imposition of all dogmatisms. They will remember that cultural and individual diversity is precious in itself, and will strive against monotonous mediocrity. They will try to ensure that the more gifted children are not bored and frustrated by being kept back, the less-gifted not made to suffer by being pushed beyond their capacities. They will hold fast to the humanist vision of variety in unity.

The increasing complexity of modern societies demands an increasing number of men and women of great ability to run them. To meet this demand, applied genetics and education must join hands. We need a comprehensive selection system to catch as many potential geniuses and top people as possible, and an educational system designed to help them realize their capacities fully.

In doing justice to human variety, educationists will be accused of encouraging an *élite*, and of promoting new class differences. That must be faced. Nature is not egalitarian; societies must always be stratified in some way; and, whether you call them an *élite* or anything else, outstanding people are needed at the top.

A proper understanding of the developmental process is important both for educators and for their political masters. Development must be studied as a natural process, not in the abstract or scholastic terms of some intrinsic vital principle or ideal purpose, nor in the reductionist terms of elements and origins. In regard to human (and animal) behaviour, the reductionists are still very vocal; orthodox psychoanalysts spend most of their time searching for origins, over-zealous behaviourists proclaim that mind is merely an epiphenomenal resultant of matter, the Skinnerian school asserts that nothing but learning is of much importance in behaviour.

We must beware of all such 'nothing-buttery'. Whenever anybody states that something is 'nothing but' something else, or is explicable 'merely' in terms of its origins, we can be sure he is wrong. In opposition to 'reductionism' I suggest 'eductionism' as a rallying cry to constructive thought in this field. It means that in considering any developmental process, we must begin with its operative function—how its end-result works. Then we can analyse it into its elementary components and search for its origins. Finally, we must examine the process itself to find out how it educes its results out of its original components.

Human development is not a mere unfolding of a miniature model; the developing human being passes through a series of radically different stages, each of them demanding different educational treatment. Yet many educational systems have insisted on treating the child as a miniature man, and others as so much blank or plastic material, to be written on or moulded at the educator's will.

The development of all organisms is a cybernetic process full of feed-back mechanisms, and produces both complexity and emergent novelty.

We are beginning to explore the mechanisms by which the genetic code inscribed in the chromosomes of the fertilized egg is translated into bodily and mental organization. An important one is what Waddington calls the canalization of development into a number of channels, each leading towards a specific kind of end-result, while any departure from their 'right' or normal course is automatically corrected.

Some more plastic canalization systems may permit the organism to wander off in various directions over the developmental landscape. This applies especially to the behaviour-systems of higher vertebrates, whose learning capacities permit them to adjust their activities to their experience.

The canalization system concerned with human behaviour is so plastic that it not only provides for an extensive wandering in later stages of development but also can be markedly influenced at its roots and in the main trunk of its growth.

It has to integrate competing and even conflicting drives and desires into some sort of wholeness. Integration can be prevented by depriving the child of some basic ingredient for proper development, as Bowlby has shown with maternal deprivation. It can be traumatically distorted by internal conflict culminating in repression, which then leads to the projection of one's own repressed aggression outwards on to others, or inwards on to oneself. An excess load of infantile guilt may produce anything from a cruel super-ego and a harsh morality to an inferiority complex and an over-meticulous conscience. A load of sexual guilt at adolescence coupled with failure to achieve social adjustment may lead to amoral and asocial indifference, to retreat into neurotic depression, or to assertion of the ego's significance by violent and antisocial actions: meaninglessness is the parent of delinquency.

Clearly educational systems cannot supply psychoanalytic treatment, nor take over from parents the job of looking after babies. But they could do much to correct infantile distortions, to by-pass adolescent frustrations, and to replace meaninglessness with significance. They could do so by providing varied opportunities for fulfilment and satisfaction, especially through activities which make boys and girls feel that they mean something, to themselves and other people.

In general, educators should try to provide children with effective systems of canalizing their own development: but how to achieve this is a matter for much research and experiment. Thus, group-projects can obviously help in giving a sense of significance; but we want to know what sort of project and what type and size of group gives what degree of significance to what kinds of boys and girls.

Meanwhile, ethology is giving a useful lead, by investigating the formation of behavioural bonds in animals. In higher vertebrates such bonds involve emotions: so they do in ourselves, but in ourselves they can be reinforced by empathy. They include the parent–offspring bond, the pair-bond tying mated birds together, the gregarious bond in bird flocks or caribou herds, the social bond in wolf-packs or rookeries.

Some important points are emerging. First, all behavioural bonds have a genetic built-in basis, but only develop to full effectiveness through some sort of learning by experience. Thus, the basis of the offspring–parent bond in monkeys is merely the experience of something soft and furry: but to make it into an operationally effective bond between a mother and her offspring, a long further chain of reciprocal experiences is needed.

Again, close and intimate relations between individuals often involve elements of hostility and fear as well as of attraction. Thus, in bird courtship, the attitudes of the mates as they approach each other are the resultant of a mixture of drives—attraction, attack, escape. These attitudes have then been seized on by natural selection and turned into formal displays serving as moves in the reproductive game. Or to take an example from a mammal which (like man) is both social and fierce, if a younger and weaker wolf is in danger during a fight, he crouches and presents the back of his head to his more powerful enemy; and this automatically inhibits the enemy's aggressive urges. The basis for this valuable bit of behaviour is built in to the genetical equipment of wolves.

All such behaviour has been largely ritualized—turned into formal activities of functional value; in the process, the element of aggression is made to serve some useful purpose, whether by re-directing it against other objects or by utilizing its energy in the performance of the bonding ceremony. Rituals are thus methods for transforming frustrating conflict situations into biologically significant activities. Clearly, something similar could be achieved in education.

All primitive societies cope with the adolescent crisis by elaborate *rites de passage*, laden with significance. Can our over-intellectual and over-technological societies not devise something similar? Could not one age-group undertake a series of challenging individual exploits, another embark on group adventures and projects, and yet another to engage in some sort of community service? Could not the end of school life be celebrated in a more significant way than now? Could not the passage to adult life be linked with the larger community of the nation and the world in something which would really deserve the title of national, or even international, service? The beginnings are there, in organizations like the Peace Corps and the Youth Conservation Corps, in exploration societies and social study-projects. We should try to link them all up into some flexible and imaginative scheme which would give outlets for many types, would provide some sense of direction to many chaotic lives, and would become an important part of the educational system.

In this, as in other ways, education could be made a more integral process, and the split between its two functions of intellectual instruction and professional training on one hand, and moral education and character-formation on the other, which began two thousand years ago with the rise of the Sophists in Greece, could be repaired and bridged.

Education still has an unfortunately low status in our competitive technological world. Yet it has a crucial role in helping the technological world through its present crisis. To-day, the overall evolutionary process, in the person of post-Darwinian man, is at last becoming conscious of itself; it is time that the educational process, in the person of the educational profession, should become conscious of itself as the essential psychosocial organ for transmitting and transforming human culture.

A first step might be the establishment of an Education Council, on a par with the Arts Council, the Medical and Agricultural Research Councils and the Department of Scientific and Industrial Research. The overriding question for such a body to consider would be this: Howe an education help in bringing coherence, significance, and direction into our fragmented, bewildered and frustrated world? It could do so in two interdependent ways: one primarily concerned with knowledge and the handling of outer experience, the other with personality and the handling of inner experience.

An obvious task is to hammer out the details of a general curriculum which would reflect the unitary vision provided by modern science and learning, and would by-pass the split between the so-called 'two cultures'; its very unity would give it a new dynamism, with sciences and humanities reinforcing each other instead of being driven into mutual hostility.

I believe that it is perfectly possible to give everybody a general understanding of what science and history and literature and industry are about, by the age of fifteen or sixteen, though it would be much easier if secondary education were extended to seventeen or eighteen: and the first year of college or university life should supplement necessary specialization with some reasonably advanced study of complementary fields.

One sub-group might study examination systems, with particular reference to methods of testing understanding as well as knowledge, and assessing creativity as well as academic performance; while another might look into ways of preventing the growth of anti-rational ideas and superstitions.

The second major study would be concerned with inner development—how to promote the growth of integrated personalities and so by-pass the split between intellectual and moral education. For this, the educational process must be designed to help children resolve their conflicts, and must provide them with opportunities not only for enjoyment but for fulfilment of many kinds.

Such a study will be difficult. It will need help from a whole range of 'ologies'—anthropology, ethology, psychology, physiology, to mention only a few. It will involve facing the problem of evil and what theologians call original sin, and reconciling some violently opposed points of view. But it could lead to new conceptions of the functions of education and a revolutionary overhaul of its methods. It could also enable education to affirm its importance as a transformer of society as well as a transmitter of culture; for the products of such a personally fulfilling education would undoubtedly press for the establishment of a Fulfilment Society.

Then there is the exciting territory of non-verbal education to be explored. There is the problem of education's link with the arts: the educational system is being called on to supply large numbers of scientists and technicians; should it be required to furnish a similar quota of artists, architects, decorators and designers? There is the question of giving schoolmasters (and, of course, schoolmistresses) opportunities for research and creative work. There is the tricky problem of tests—intelligence tests, open-ended tests, imagination tests, personality tests. There is the problem of how far meditation could replace or supplement formal religious services.

Then there is the world problem. The world has become one *de facto*: it must achieve some unification of thought if it is to avoid disaster, and this can only come about through more and better education. Yet more than half the world's total population is still illiterate, and its provision for education at all levels is grossly inadequate. The under-developed countries are all demanding more and better education. Britain, as an ex-colonialist country and the senior partner in the Commonwealth, has a special responsibility for meeting these demands.

In the background there looms the great question-mark of so-called adult education. With the combination of more automation, more compulsory leisure and greater spending power, we shall soon have to extend our educational system to meet the continuing needs of the entire adult population: perhaps we should envisage a National Education Service.

Obviously, our university departments of education will be required to enlarge their functions, and will become the academic agencies of the educational system. By fully establishing the claims of education to equal rank with other subjects in the university curriculum, both as a field of research and as a course of study, as well as training for a job or a career, they could do much to improve its public image.

* * * *

It is a strange and rather disturbing fact that in the one-volume abridgement of Toynbee's monumental *Study of History* there is only one short section on education. If the educational profession is successful in meeting the challenge of the new knowledge and the new vision which it reveals, later histories of mankind will not only devote much more attention to education as a major social function but will also single out our age as the historical moment when education was reorganized as an integral part of the psychosocial process, and became pre-eminent among all the agencies concerned with human destiny.

BIOSYNTHESIS OF PROTEIN-VITAMIN CONCENTRATES FROM PETROLEUM

By A. CHAMPAGNAT, C. VERNET, B. LAINÉ and J. FILOSA
Société Française des Pétroles BP, Paris

IN 1957, a microbiological research organization was founded at Lavera with the aim of studying the possibility of using micro-organisms for the treatment of petroleum fractions. These investigations soon showed that a large variety of microbes were able to live and reproduce themselves actively at the expense of hydrocarbon mixtures, not only in laboratory cultures but also at the bottom of storage tanks, in refinery settling beds, in soils saturated with oil and even under bituminous road surfacings. These micro-organisms have a high protein content.

On May 22, 1959, at a meeting of l'Association Nationale de la Recherche Technique, which was held for the purpose of suggesting broad themes of fundamental research to the Comité Consultatif de la Recherche Scientifique, one of the present authors (A. C.) proposed "Microbiology with Respect to the Conversion of Petroleum into Proteins"[1].

The microbiological research of the Société Française BP was directed to this problem and for two years the laboratory at Lavera has been producing small quantities of protein concentrates analogous to animal proteins and rich in growth vitamins. It has been found that the petroleum fractions used as a substrate for the cultivation of the chosen micro-organisms are extensively dewaxed by these micro-organisms. There are thus new possibilities from the point of view of the petroleum refiner, in addition to the production of protein-vitamin concentrates in place of waxes since wax is sometimes undesirable because of its tendency to crystallize out in cold weather. The transformation of the paraffinic hydrocarbons metabolized into protein-vitamin concentrates may reach a 100 per cent yield as a result of the fixation of atmospheric oxygen by the hydrocarbons/from biosyntheses which elaborate cellular material. Nitrogen, phosphorus, potassium, and trace elements, all of which are indispensable, are supplied by fertilizers and by low-priced chemical products in an aqueous nutritive medium.

Proteins are present in appreciable amounts in cereals such as wheat, maize, rice, etc., which are the basic and often the only foodstuffs for the majority of the world's populations, either because of poverty or through ignorance of nutritional requirements. But the amount of amino-acids essential for life (that is, those which the human organism is incapable of synthesizing) which these proteins contain is very low. Only in animal proteins are these amino-acids found in sufficient quantity, and in the requisite proportions. However, it has been found that the majority of micro-organisms are capable of performing this same synthesis, with a product distribution approaching that found in animal proteins.

Table 1 gives the composition of a typical protein-vitamin concentrate prepared at Lavera and examined at length. Table 2 gives details of the distribution of the essential amino-acids present in this concentrate and, for comparative purposes, in various basic foodstuffs. Table 3 gives the vitamins contained in the concentrate, in comparison with those of various foodstuffs.

Although the carbohydrates and the fats present are also of interest nutritionally, it is the essential proteins and the water-soluble vitamins which give the new foodstuff its value.

Table 2 shows first of all that the wheat proteins are gravely deficient in lysine. This amino-acid is found in requisite proportion only in animal proteins: meat, fish,

Table 1. BP Protein-vitamin Concentrate

	Analysis (per cent by wt.)
Moisture	7·03
Dry matter	92·97
Total nitrogen	6·92
Proteins	43·6
Lipids	18·5
Carbohydrates (starch)	21·9

BP protein vitamin concentrate	8–16*	75	180–200	150–192	23	0·11

Quantities of vitamins are expressed in mg/kg: they were taken from refs. 1, 4, 5.

* Dependent on conditions of drying the final product.

milk, and also in yeasts. "Lysine in particular is the limiting factor for the growth of animals. Cereal proteins are lamentably poor in lysine"[1] with the exception of soya. Thus a cereal without any supplementary material is not a good foodstuff for cattle[1], or for human beings. Addition of lysine to cereal foodstuffs is now normal practice[5]. The proteins of the new concentrate are related to animal proteins and more closely to those of yeast, the nutritive quality of which is already well established. The concentrate is, in fact, produced by a variety of yeast which has adapted itself to petroleum.

The composition of the protein-vitamin concentrate shows that it can supply the essential proteins and the growth vitamins at one and the same time to mixed foodstuffs. Its richness in riboflavine (vitamin B2) and in pantothenic acid gives it an exceptional value from this point of view.

Nutritional tests are in progress on populations of rats and chickens. The growth of these animals is being compared with that of control animals which are receiving conventional protein rations.

The daily human requirements for animal protein are 30 g for adults, 70–100 g for pregnant women, nursing mothers, and children[6]. In order to satisfy these requirements in full, it would be necessary to make up an annual world deficit in animal protein of the order of 3 million tons[7]. This would correspond to 15 million tons of lean meat. It is not very likely that the cultivation of new land followed by the raising of selected strains of cattle could realize this production within a period of (say) 40 years. In 40 years time, however, the present world population of 3 thousand million may well have doubled.

From a ton of normal paraffins, which do not need to be separated from the petroleum fraction which contains them, it should be possible to obtain a ton of the protein-vitamin concentrate containing 45–50 per cent protein. At the same time, the corresponding petroleum fractions are dewaxed and in certain cases their value is increased.

For an annual production of 1,000 million tons of crude petroleum, it may be assumed that 700 million tons are paraffinic. The production of 7 million tons of protein-vitamin concentrate (equivalent to 3 million tons of proteins) would consume only 1 per cent of these 700 million tons of crude. An ample supply of raw material is therefore available. The time required for the construction of petroleum fermentation units would be about 1–2 years.

The rate of production of proteins by the new process may be compared with that for proteins produced naturally in the conventional manner: one 500-kg cow suitably fed by grazing synthesized 0·5 kg protein in 24 h[8]. 500 kg of living micro-organisms in a continuous fermentation unit, suitably fed with hydrocarbons, nitrogen, phosphorus, potassium and air, should produce, according to our experience, 2,500 kg micro-organisms in 24 h, which may be 1,250 kg protein. Industrial production may thus be 2,500 times as fast as the natural method.

We thank Dr. Jacques Senez of the Centre National de la Recherche Scientifique for his contribution to the fundamentals of this work.

NOTIONS OF NICHE AND COMPETITION AMONG ANIMALS, WITH SPECIAL REFERENCE TO FRESHWATER FISH

By DR. A. H. WEATHERLEY
Zoology Department, School of General Studies, Australian National University, Canberra

CONCRETE definitions will be offered here of the terms 'niche' and 'competition'. Both notions have been fruitful 'operational concepts' in ecology for many years; but for lasting usefulness their scope should be delineated more clearly, even though this will inevitably be a somewhat arbitrary undertaking. The terms may then continue to serve, since their more felicitous application will become possible, even if their use is more limited, because more strictly prescribed.

Elton[1], probably the first to popularize the use of the term 'niche' in animal ecology, certainly appears preeminent in applying it mainly to an animal's nutritional status in its ecosystem. He also included, in the meaning of the niche, the animal's relations to other animals, and its general space occupancy. It has long been common to use the word in some very broad sense, and in my view it is this comprehensiveness or inclusiveness of meaning that threatens the usefulness of the term because it reduces its precision of application. Thus, other authors[2–4] besides Elton have considered the niche mainly as the complex of environmental conditions under which the organism lives—conditions among which it may, indeed, be obliged to live through having become adapted to them—and the manner in which it lives among them. It is thought that by thus living under these 'niche' conditions the organism may continue to exploit the environment in various ways that permit the survival of it and its progeny.

Dice[5] departed from a formal point of view so far that he failed to restrict, or specify with any adequacy, the meaning he attached to the niche. However, he did claim that "The term does not include, except indirectly, any consideration of the function the species serves in the community", whereas, as Odum[3] points out, Elton pioneered the use of the "term 'niche' in the sense of the functional status of an organism in its community".

Sometimes the meaning of niche has been cast in such broad terms as to make it almost useless to the ecologist. As Bodenheimer[4] wrote: "It is erroneous to expand it to a meaning synonymous with ecoworld. . .". After all, this is virtually to make niche substitute for ecology itself, or anyway a large part of ecology.

It is proposed that if the niche be retained as a valid concept in ecology its value as a tag or label be borne in mind. Elton[1] used the term to label an animal's characteristic role in the ecosystem, especially with respect to the foods it ate and the importance of this for other organisms of the ecosystem. Elton pointed out that in ecosystems widely separated from each other—a continent, even a hemisphere, apart—remarkable parallels in niche occupancy could occur among animal forms that were widely different in the systematic sense. He wrote that there is a "rabbit niche . . . filled by rabbits and hares in the palaearctic region and in North America, by the agouti and viscacha in South America, by wallabies in Australia and by . . . the hyrax, the springbok, and the mouse deer in Africa". A conception of the niche as powerful as this provides excellent means for deriving profitable abstractions about ecosystems. For example, in comparative surveys ecologists are often faced with a difficulty of finding common underlying facts or principles that will indicate presence or absence of essential similarities between different ecosystems. The amount of parallelism or diversity between the niches occupied in the different ecosystems would go far towards revealing basic similarity or divergence of ecological constitution. If restricted to an organism's feeding relations the niche concept will be of most value, as it is on a common fabric of available food that all patterns of animal activities are worked out. Modern studies on the ecology of production can benefit if the niches of the various organisms of the ecosystem are well known. Furthermore, the completeness with which two or more species occupy the same niche is of great importance in evaluating competition between them.

The following definition of the niche is proposed: The niche is the nutritional role of the animal in its ecosystem, that is, its relations to all the foods available to it.

Since we are concerned especially with the relevance of the niche for freshwater fish, it is important to show that at least some of them actually occupy niches.

Das and Moitra[6,7] described alimentary systems of various tropical species from the Uttar Pradesh, India. There were many omnivores, and also strongly carnivorous and herbivorous species. The findings are briefly set out as follows:

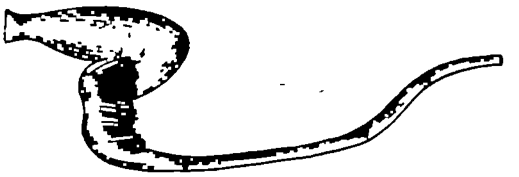
(*a*) Herbivorous fish lack teeth, but possess fine gill-rakers that can sieve microscopic plants from the water; they lack a true stomach, but have a long, thin-walled intestine.

(*b*) Carnivorous fish have teeth well developed to seize, hold and tear; gill-rakers are modified to grasp, retain, rasp and crush prey; there is a true, flask-like stomach for trituration and storage of food, and the intestine is short and elastic with thick walls.

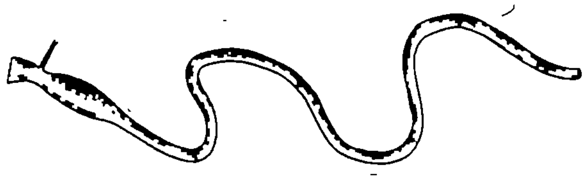
(*c*) Omnivorous fish have alimentary systems more or less intermediate in form between the herbivorous and carnivorous extremes.

These authors also found that, relative to body-length, the alimentary canal was much longer among herbivorous than carnivorous fish, with the omnivores again occupying an intermediate position.

Many fish species of Lake Nyasa have remarkable adaptations of mouth structure to feeding habits[15]. Perhaps most striking of these, *Genyochromis mento*, lives on scales and fin-rays of other fish, thus occupying an extremely narrow niche.



Salmo trutta



Carassius carassius

Fig. 1. Morphology of the alimentary canals of two temperate species of freshwater fish, showing adaptation to dietary habits

It is easy to find similar adaptations of the alimentary system among freshwater fish of temperate regions. Thus the brown trout is strongly carnivorous, while the crucian carp feeds heavily on algae and detritus of largely vegetable origin (Fig. 1). In these forms, as with the tropical Indian fish, morphological differences clearly reflect dietary differences.

Another sort of evidence in support of the niche can be found by examining data on biomasses of fish in many reservoirs in the mid-western United States[8]. It was found that total biomass tended to increase with number of species present in a community. This suggests that the tendency for different species to occupy different niches permits several or many species to utilize more completely the total food resources of the environment, than can one or a few species, resulting in higher total biomasses.

Notwithstanding the evidence that many freshwater fish occupy fairly definite niches, there are many others the wide, variable food habits and unspecialized alimentary systems of which practically preclude their having clear-cut niches. Several investigations have indicated[9–11] that multispecific fish communities can exist stably. Fish species in communities of this sort, though most of them are drawing on one general supply of food, may engage in sporadic and unpredictable changes of diet and can scarcely be thought of as occupying definite and discrete niches. Thus while many fish species may be firmly assigned to a niche, others cannot be so treated.

This article is concerned with competition for food among fish, and with the relations between competition and the niche. Before considering this latter topic, a definition of competition must be decided on, and evidence advanced of its existence among freshwater fish.

Recently, the conceptual confusion that surrounds competition was clearly shown[12]. Furthermore, there has long been a tendency to infuse definitions of competition with a flavour of 'conflict'. Thus Odum[3] has suggested that competition is an interaction between species "in which each population adversely affects the other in the struggle for food, nutrients, living space, or other common need". Key words here are 'adversely' and 'struggle'. Harper has been quoted[13] as proposing that "Competition is the endeavour of two (or more) animals to gain the same particular thing, or to gain the measure each wants from the supply of a thing when that supply is not sufficient for both (or all)". Apart from the highly questionable use of such words as 'endeavour' and 'wants' in the second definition, there resides in both an implication that competition will result in advantage or sufficiency for one species, with the opposite results for others. This objection can be avoided[13]: "Competition is the demand, typically at the same time, of more than one organism, for the same resources of the environment *in excess of immediate supply*". This is not a perfect definition, being somewhat marred by the ambiguousness of the final clause (italicized); but, if this is deleted, it is satisfactory in telling what competition is about, without the objectionable feature of going on to predict what its results may be. This sort of thing is a weakness in any definition, since the more inclusive a definition is made the greater will be the likelihood that exceptions to its application will arise.

The idea of deleterious effects arising from competition for food among fish must, in general, be set aside. This is mainly because fish have such flexible growth rates. The growth of fish in Nature is largely dependent on density of population. This is well shown for pond fish[14] and Beckman's work[15-17] elegantly shows the stimulus to growth of lake fish communities, of several species, that followed massive field mortalities. Recently[18] there has been clear evidence of greatly increased growth of perch in Windermere resulting from drastic lowering of population density through many years of trapping. These are just selected examples to illustrate the general relationship. They invite the inference that fish compete for food, so that intensity of competition is also dependent on density. The further inference follows that growth rate may be increased, without lowering population density, by artificially stimulating the production of organisms on which fish feed. This has, in fact, been accomplished for both pond and wild populations of fish on a number of occasions[19-21].

Andrewartha and Birch[22] emphasized the scarcity of 'direct' evidence of competition in Nature; but as with many ecological realities, the kind of interaction which can be called competition is usually recognizable mainly through its effects. It is not the less real for this.

The actual nature of competition will vary. Sometimes competitive interaction may be of that very direct kind where two animals actually struggle together over a single food item. Probably it more frequently takes the form of a behavioural inhibition that limits feeding territory. However, its precise character in a given instance is not of general significance for ecology. Fig. 2 is an attempt to show what happens to assimilation (growth, weight increment) in a fish population as numbers increase. There will be some critical low population density below which effects of competition for food will not be present, that is, the fish will be assimilating at their maximal rate for that particular set of environmental conditions. Now given a certain level of available food, the principal limitations to a fish's feeding capacity reside in the efficiency of its feeding organs (mouth, teeth, gill-rakers, alimentary canal) and in its feeding habits. The principal limitations to its assimilative capacity reside in the balance between its catabolic and anabolic physiology, which also involves the matter and energy it must consume in its search for food. At a critical level of population density varying with the species involved, fish will begin to interact significantly with each other, so that their feeding habits are interfered with, and the distance they must travel to find food will, on the average, be increased. This will result in a change in the balance between catabolism and anabolism, and assimilation will decrease, and will continue to decrease with increasing population density (that is, intensity of competition). These principles will operate whenever fish are competing for the same food, and will therefore operate at both the intra- and inter-specific levels. The most complete form of competition for food will obviously take place between species occupying much the same niche, that is, eating much the same food in the one environment.

Many modern ideas about the niche and competition stem from highly artificial laboratory experiments, such as the famous studies of Gause[23] on protozoans. Thus Odum[2] provides several examples of natural populations of organisms where the 'Gaussian' principle, that more than one species cannot continue to occupy the one niche, can be used to explain or interpret differences in distribution between species. Now the fact that in this article the niche has been defined somewhat strictly, and has a more restricted scope for application than is usual, does not permit us to beg the question implied by the investigations mentioned above. This question is, essentially: Where two (or more) species are eating exactly the same kind of food in the same ecosystem, occupying the same general space at the same time, and exploiting the same habitat conditions, will one species eventually extinguish the other(s)? Fryer[24] has, indeed, asserted that among herbivorous fish of Lake Nyasa: "Several closely allied species co-exist in the same micro-habitat and take the same food". His explanation is that: "Such co-existence is at variance with the so-called Gaussian hypothesis and seems possible because of a superabundance of the algal food on which the species feed". This is a possible interpretation; but perhaps Fryer rather overlooks the fact that the essential consequences of competition for food among fish, whether at the intra- or inter-specific level, are lowered growth rate rather than density-dependent mortality effects. Even if two fish species occupy the same general space and habitat (as Fryer believes his fish to do) eventual extinction of one of the species need not follow. If some females were impaired in their spawning through overcrowding, this might lower recruitment; there is little reason to think that the lowered population densities that would eventually result would be serious for either competing species.

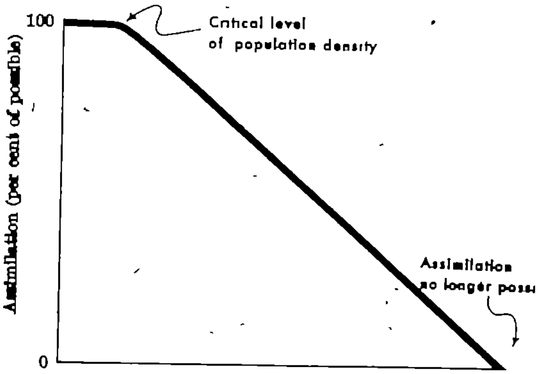


Fig. 2. Dependence of assimilation of food by freshwater fish on population density

Of course, for the multi-specific fish communities of no fixed feeding habits, which have already been mentioned, competition would probably never be more than a fleeting problem. These fish change their diets so readily and can grow satisfactorily on such a wide range of items that they are scarcely likely to suffer prolonged disadvantage from competition-induced food shortage. In addition, in these communities, through differences in behaviour, general habitat preference, activity patterns (which may or may not include seasonal migrations), oviposition sites, etc., few species indeed will be likely to occupy persistently the same space as others.

OBITUARIES

Dr. G. H. Cunningham, C.B.E., F.R.S.

GORDON HERRIOT CUNNINGHAM, pioneer in plant pathology and taxonomic mycology in New Zealand and formerly director of the Plant Diseases Division, Department of Scientific and Industrial Research, died at Auckland on July 18, 1962.

Born at Moa Flat, a high country sheep station in Central Otago, New Zealand, he spent his childhood in the wide spaces of the tussock lands, which induced in him a lasting love of outdoor life. He received his early education at the local Dunrobin school and at Tapanui High School.

As a young man he gained wide practical experience in sheep farming, fruit growing and forestry work in both New Zealand and Australia. During the First World War he served with the New Zealand Expeditionary Forces, but, after being wounded during the Gallipoli campaign, he was invalided home.

Debarred by his injuries from rejoining the Armed Forces and being keenly interested in fruit growing, he joined the New Zealand Department of Agriculture as an orchard instructor in 1917, the year in which he met Madge Leslie McGregor, whom he married the following February. Cunningham's knowledge of, and interest in, the diseases of fruit trees so much impressed the director of his Division that he was transferred (in 1918) to the Department's Biological Laboratory at Weraroa, near Levin, to specialize in plant pathology. Realizing the need for academic training, he requested permission to attend university and moved to Wellington early in 1920.

This was the beginning of an extraordinarily active career in plant pathology and systematic mycology. During the eight years he was stationed at Wellington, while fulfilling his normal duties as plant pathologist, he passed his university entrance examinations and gained the degrees of B.Sc. (1924), M.Sc. (1925) and Ph.D. (1927). He published his first book, *Fungous Diseases of Fruit Trees in New Zealand* (1925), wrote thirty papers on plant pathology and thirty-two on taxonomic mycology, made disease surveys throughout the country and many excursions into the field to collect specimens for the establishment of a herbarium of New Zealand fungi. His taxonomic research, which included systematics and developmental studies of the Ustilaginales, Uredinales, Gasteromycetes and Polyporaceae, set a pattern for his later work within the Basidiomycetes. During the winters he visited the main fruit-growing areas to lecture to orchardists on the diseases of fruit trees. In 1924, on the recommendation of Dr. E. J. Butler, director of the Imperial Mycological Institute, London, who had visited New Zealand the previous year, he was sent to England to represent the Dominion at the first Imperial Mycological Conference.

When agricultural research was re-organized in 1928 and the Plant Research Station was formed with headquarters at Palmerston North, Cunningham was placed in charge of the Mycological Laboratory of the new institution. In the following year he attended the second Imperial Mycological Conference in London, visiting research institutions in Britain, on the Continent and in North America. This enabled him to meet most of the world's leading plant pathologists and fungous taxonomists, contacts which had a lasting influence on his work. During the eight years that he was in charge of the Mycological Laboratory he organized a team of plant pathologists to work in the fields of economic mycology, bacteriology, virology, plant physiology and plant protection. He continued his systematic mycology, and in addition to writing many taxonomic papers he published his book, *The Rust Fungi of New Zealand* (1931), for which he was awarded the degree of D.Sc. At the same time, he maintained a keen interest in plant-pathology and published articles dealing with chemicals used for the control of plant diseases and pests. This work culminated in 1935 in the publication of a book, *Plant Protection by the Aid of Therapeutants*. In the same year he was awarded the Hutton Memorial Medal for research in mycological botany.

A further re-organization was made in 1936 when plant research was transferred from the Department of Agriculture to the Department of Scientific and Industrial Research. A Plant Diseases Division, responsible for plant pathology, entomology and pomological aspects of fruit growing, was formed, Cunningham becoming its director. His first task, apart from choosing a suitable site in Auckland, was to plan buildings for the new Division. A modern laboratory block on the slopes of Mt. Albert was ready for occupation in January 1938. Although much of his time was taken up in planning and organizing during this period, he still continued his research, producing a steady flow of scientific papers and reports.

With the formation of the Plant Diseases Division, the acquisition of land and erection of laboratories, Cunningham, for the first time in his career, had adequate facilities to pursue his ideal of creating a plant protection service adequate to the Dominion's needs. He introduced, in 1938, a voluntary therapeutant certification scheme which revolutionized chemical control of diseases and pests in New Zealand. It was also through his encouragement and assistance that the New Zealand Fruitgrowers' Federation, Ltd., established a Fruit Tree Nursery at Levin, from which, for the past twenty years, orchardists have been able to secure pedigree fruit trees growing on improved rootstocks.

In spite of the difficulties in organizing a plant protection service, he still found time for his taxonomic studies and began to prepare the manuscript of a book on the Gasteromycetes of Australia and New Zealand. The development of the Division, however, suffered a severe setback with the outbreak of the Second World War. As a veteran of the First World War, he viewed sympathetically his staff's desire to join the Armed Services. As soon as permission could be secured, therefore, more than half his trained professional staff volunteered for active service. His own particular contribution was to the linen flax industry, which operated at that time in the Dominion.

With the War over and his officers returning from duty overseas, he set about rebuilding his plant protection organization. He also again took up his taxonomic studies, his book, *The Gasteromycetes of Australia and New*

Zealand, appearing in 1944. In 1948 he was awarded the Hector Medal, and in 1949 the C.B.E. In 1950 he was elected a Fellow of the Royal Society.

During the ten years before his retirement in 1957 at the age of sixty-five he devoted much time to the study of systematics. Although he died when he was sixty-nine, in those four years he prepared the manuscripts of one book on the Thelephoraceae and another on the Polyporaceae of Australia and New Zealand. The former is due to appear early in 1963, while arrangements have been made to publish the latter.

Dr. Cunningham was a man of great physical and mental energy. In his youth he earned a reputation both as a boxer and as a racing motor-cyclist, and in later life became a keen mountaineer. An indefatigable collector, until his last illness he spent much time in the field gathering material for the Plant Diseases Division Mycological Herbarium which, begun by him more than forty years ago, is now one of the finest in the southern hemisphere. His work was characterized by a remarkable perception and soundness of judgment. This is shown by the fact that his early papers in both plant pathology and systematics were, even on present-day standards, of exceptional merit. In addition to 220 scientific papers, including six books, he wrote a biography on the life of Squadron Leader McGregor—*Mac's Memoirs*. He had an absorbing interest in farming with a keen desire to assist the man on the land. A delightful companion, he will be greatly missed by his many colleagues and friends throughout the world. To science his death is a very serious loss, but his huge output of work is a monument in itself. He is survived by a wife and married daughter.

E. E. Chamberlain

Prof. E. J. King

Earl Judson King, professor of chemical pathology in the University of London at the Postgraduate Medical School, died suddenly at his home in London on October 31, at the age of sixty-one years.

Prof. King was born in Toronto in 1901, the son of the Rev. C. W. King. He was a student at Brandon College and then attended McMaster University, where he graduated with honours in chemistry and biology. He then proceeded to the master's degree in chemistry and, having been awarded a National Research Council bursary, went to work with Prof. F. B. Allan in the University of Toronto, where he obtained his Ph.D. in 1926. During the following year he was research associate in the Department of Medical Research at Toronto and then entered the Banting Institute in 1927. While here he spent two periods of leave of absence—one at the Lister Institute in London and the other at the Kaiser Wilhelm Institut in Munich. He returned to Toronto as assistant professor of medical research and director of the Biochemical Section of the Banting Institute. In 1934 he was invited to become reader in pathological chemistry and head of the Chemical Pathology Department at the newly founded Postgraduate Medical School of London. He took up these duties in 1935 and was appointed professor of chemical pathology in 1944. He was admitted to the fellowship of the Royal Institute of Chemistry in 1948 and appointed an examiner in 1952. He eventually obtained the degree of D.Sc. of the University of London.

Prof. King's two major scientific interests were concerned with research on silicosis and the phosphatase enzymes. In each of these fields he gained world-wide recognition. The work on phosphatase was commenced at the Lister Institute with Robison in 1929 and later in Toronto with A. R. Armstrong he devised the well-known method for estimating alkaline phosphatase in blood. The King–Armstrong unit has become a household name in all laboratories concerned with clinical chemistry. In this respect, it is interesting that Prof. King was the main originator of proposals to define enzyme units on a more rational basis, which would mean that the unit with which his name was associated would be abolished. The work on phosphatase could justly be regarded as the forerunner of the general use of enzymology in clinical practice as well as in clinical research.

During his period at the Postgraduate Medical School, Prof. King developed many of the micro-chemical methods now in use in clinical chemistry and did much to introduce photo-electric equipment concerned with colorimetry, flame photometry and automatic analysis. He was a constant inspiration to those who worked with him; a notable number of people who worked in his Department have achieved senior status. One of the most admirable aspects of Prof. King's character was the great trouble to which he went to help promote the interests of the junior members of his staff as well as the encouragement he gave them.

Prof. King served with distinction on a remarkably large number of committees and held many administrative appointments. He was one of the founders and the first secretary of the Canadian Biochemical Society. He was appointed sub-dean of the Postgraduate Medical School in 1944. He was secretary of the Board of Studies in Biochemistry in the University of London during 1943–46 and served as chairman from 1951 until 1955. He also served as chairman of the Committee on Clinical Chemistry of the International Union of Pure and Applied Chemistry and was president of the Biological Section. He was chairman of the International Federation of Clinical Chemistry during 1952–60 and chairman of the Central Academic Council of the British Postgraduate Medical Federation from 1952 until 1955. He was president of the British Occupational Hygiene Society (1954–55) and chairman of the Editorial Board of the *Biochemical Journal* from 1946 until 1952. In 1957 he became chairman and director of the Postgraduate Medical School's combined Departments of Bacteriology, Biophysics, Chemical Pathology, Hæmatology and Morbid Anatomy and Histology.

He played a great part in the formation of the Association of Clinical Biochemists; he was chairman during 1953–55 and president in 1956.

In addition to numerous scientific papers, Prof. King published *Chronic Pulmonary Disease in South Wales Coalminers: III—Experimental Studies* (M.R.C. special report) and was the original author of *Micro-Analysis in Medical Biochemistry* and co-editor (with R. H. S. Thompson) of *Biochemical Disorders in Human Disease*.

During the Second World War he was sector chemical pathologist in the Emergency Medical Service and consultant in pathology to the R.A.M.C. In 1945 he went to India with the rank of brigadier to act as adviser on chemical pathology.

Among numerous honours that he received were life membership of the American Association of Clinical Chemists, the Queen's Coronation Medal, honorary membership of the Canadian Physiological Society, and the Canadian Society for Clinical Chemistry. He was the recipient of a number of honorary degrees, including an honorary M.D. by both the University of Oslo and the University of Iceland. These latter were more than appropriate, since Prof. King had contributed so much to medicine.

Earl Judson King was typically colonial in his manner. He was always very forthright and direct, but, nevertheless, the kindliest of men, who made friends throughout the world. He was an extraordinarily good host and it was in this role that many obtained their first glimpse of the remarkable breadth of his culture.

Although during the last years of his life he suffered from serious illness, this was only allowed to interfere with his activities as little as possible.

In 1927 he married Hazel Keith, a former class-mate at Brandon College. He is survived by his wife and two daughters.

A. L. Latner

Dr. F. U. Klaehn

Dr. Friedrich U. Klaehn, associate professor of sylviculture at the State University College of Forestry at Syracuse University, died suddenly of a heart attack in Crouse-Irving Hospital on October 21, aged forty-six.

An international authority on forest tree genetics and efforts to improve forest tree species, Dr. Klaehn was born and educated in Germany. He was a native of Essen-Steele, Ruhr, where he was born on October 27, 1915. He was a holder of forestry and Ph.D. degrees from the University of Göttingen, Göttingen, West Germany. His two degrees were earned in 1949 and 1950, respectively. He went to Syracuse on his appointment to the College of Forestry faculty on October 1, 1955. He was a member of the faculty and research staff of the Department of Silviculture.

He is survived by his widow, the former Miss Ingrid H. Schrader, two children and his parents.

Dr. Carl R. Eklund

Dr. Carl R. Eklund, noted Antarctic explorer and chief of Polar and Arctic research for the United States Army, died suddenly on November 4, 1962, in Philadelphia, where he had been lecturing at the Museum of Natural Science. He was fifty-three years old.

A native of Tomahawk, Wisconsin, he was given the key to the city last year as an "honoured son", during its Diamond Jubilee celebration. Dr. Eklund graduated from Carleton College in Minnesota, in 1932, and began his twenty-nine years of Government service as a forestry foreman in Virginia's Shenandoah National Park. In 1936, he transferred to the Fish and Wildlife Service as a research biologist and ornithologist, serving in various locations, including Michigan, Oregon, Illinois, and Washington. He received his master's degree from Oregon State College in 1936. During the Second World War, he served as a major in the Arctic section of the Arctic Desert Tropic Information Center of the Army Air Forces and was assigned to missions in Greenland and Canada. His last post with the Fish and Wildlife Service before his resignation in 1957 was as assistant regional director in Atlanta, Georgia. During the International Geophysical year, 1957–58, Eklund served for eighteen months as scientific leader at Wilkes Station, Antarctica. His thesis for his Ph.D. degree at the University of Maryland in 1959 was based on his work at Wilkes, where he solved the mystery concerning the penguin egg's incubation temperature by 'borrowing' an egg from the Adelie penguin, implanting a tiny temperature sensor and radio transmitter, and replacing the egg in the nest. He then monitored its average temperature, which he found to be 92·7 degrees, only 11·1 degrees lower than the body temperature of the bird which was incubating them, despite the surrounding sub-zero temperatures. In 1958, on his return from the Antarctic, he was appointed chief of the Polar and Arctic Branch of the Army Research Office.

Dr. Eklund made his first trip to the South Polar continent during 1939–41 as a member of the late Rear-Admiral Richard E. Byrd's expedition, during which he and Finn Ronne made one of history's major Antarctic treks. They travelled 1,264 miles by dog-sled in 84 days, charting and mapping more than 350 miles of the Antarctic coast, and discovered a group of islands in King George VI Sound, which has since been named the Eklund Islands. He and Ronne also determined that Alexander I Land is an island, linked to the mainland only by floating ice in a trough more than three times the length of Long Island Sound.

Dr. Eklund received international recognition for his work as an explorer and scientist. Recently he had returned from Paris, where he was an official representative of the Committee on Polar Research of the United States National Academy of Sciences. He was a member of the Explorers Club and was founder and first president of the Antarctican Society in Washington, D.C.

Dr. Eklund will be missed by his many friends and colleagues. He was one of the rare men who had no enemies; he had a great sense of humour and a kind attitude to his fellow man which made him a valued companion.

He is survived by his widow, Harriet, and two daughters, Linda and Signe.

Kaare Rodahl

Mr. N. M. H. Lightfoot

Nicholas Morpeth Hutchinson Lightfoot, principal of the Chelsea College of Science and Technology, died on November 20 at the age of sixty. Lightfoot was educated at Jarrow Grammar School, Co. Durham, proceeding from there by scholarship to Jesus College, Cambridge, to read mathematics. During 1929–43 he served on the mathematics staff of the Heriot-Watt College, Edinburgh, first as lecturer and later as head of the Department. In 1943 he was appointed principal of the South-East Essex Technical College, Dagenham. He moved to Chelsea in 1950, where he was principal until his death.

At the beginning of his career he published papers on the mathematical theory of cooling steel, but later became primarily a teacher and then administrator.

During his long service as principal, first at Dagenham and later at Chelsea, he played an active part in matters concerning technical education and was elected president of the Association of Principals of Technical Institutions in 1955–56. He also served on the National Council for Technological Awards, the Parliamentary and Scientific Committee and the Regional Advisory Council.

His period as principal at Chelsea was marked by rapid developments in the College as the result of the change of status to a College of Advanced Technology, by which the old Chelsea Polytechnic became the Chelsea College of Science and Technology. This change required important decisions as to the proper direction for the future of the College. Up to the time of designation as a college of advanced technology, the College had been providing courses mainly for internal degrees of the University of London in science and pharmacy. Unlike all the other colleges of advanced technology, there was no school of engineering. It was chiefly as a result of Lightfoot's deliberations that the College continued to provide courses such as were traditional, but to develop research and postgraduate courses of an applied nature. Because of this decision, Chelsea College has a higher percentage of postgraduate work than any other college of advanced technology despite great limitations of space. In this way, Lightfoot felt that the College would play a proper part in its new capacity.

As a man, Lightfoot was quiet and retiring in his behaviour. In all that he did he was extremely conscientious with a sharp eye for detail. He came to a decision only after mature thought, but once he had made up his mind he went ahead with determination. He was a man of the highest integrity and because of this his staff knew that he could always be trusted. Likewise, he never interfered with his heads of Departments, leaving it to them, as experts in their own particular fields, to run their departments in their own way. In his unobtrusive way he has left his mark on the College and he will be sadly missed.

Lightfoot's death came tragically soon after that of his wife in December 1961, and our sympathies go out to his only daughter in losing both her parents in so short a time.

C. C. Hentschel

Mr. E. C. Stubbens

Ernest Charles Stubbens, who died on November 16 at his home in Shelford, was born in Cambridge on May 3, 1899. He began a lifetime devoted to the scientific instrument industry with an apprenticeship to the Cambridge Instrument Co., which he entered in 1913. After two years in the armed forces in the First World War, Mr. Stubbens spent four years with British Thomson-Houston Ltd. in Rugby but took an early opportunity of returning to his native city when he was appointed chief inspector with Pye Radio Ltd. in 1925.

In August 1934 Mr. Stubbens joined Unicam Instruments, the new enterprise started a few months earlier by his brothers, the late Mr. Sidney Stubbens and Mr. John Stubbens, who is the present head of the model shop at Unicam. Pioneer conditions made it possible—essential even—for "E. C. S." to show his many talents, and he served his new company in several capacities before finding his true métier when, during the Second World War, he took charge of production at the London Instrument Co., seconded to Unicam for the duration. At the end of hostilities he returned to the main Unicam factory as works manager and began the happy association with old colleagues and new friends that has now come to an end.

He held strongly to the belief that efficiency is closely related to congenial working conditions and set himself to create both, as much by his personal example as by his executive activities. His success contributed largely to the major expansion of Unicam in recent years. A lively personal interest in the welfare of his staff found expression in his work as chairman of the Company's Sports and Social Club, to which he devoted his time and energies in full measure.

Mr. Stubbens leaves a widow to whom his many friends extend their profound sympathy.

NEWS and VIEWS

Soil Mechanics at Manchester: Prof. P. W. Rowe

Dr. Peter Walter Rowe, at present reader in soil mechanics in the University of Manchester, has been granted the status of professor of soil mechanics at that University. Dr. Rowe went with a Merchant Venturer Scholarship from Bristol Grammar School to the University of Bristol, where he graduated with first class honours in civil engineering in 1942. After three years as a junior scientific officer at the Royal Aircraft Establishment, Farnborough, he joined Sir Robert McAlpine and Son, Ltd. In 1947 he was appointed lecturer in civil engineering at University College, Dundee, where he conducted research on anchored sheet pile bulkheads, for which he was awarded the degree of Ph.D. Dr. Rowe went to Manchester in 1952 as a lecturer in engineering and was promoted to a senior lectureship in 1954. He was awarded the degree of D.Sc. in 1956 and was appointed reader in soil mechanics in 1958. He has organized in Manchester short postgraduate courses in soil mechanics which have attracted senior workers from many parts of the United Kingdom and abroad. He has lectured widely in the United States and at international conferences.

Genetics at Liverpool: Prof. P. M. Sheppard

Dr. P. M. Sheppard, reader in genetics at the University of Liverpool, has been appointed to the newly established chair of genetics at that University. Dr. Sheppard, who is forty-one years of age, was educated at Marlborough College and at Worcester College, Oxford, where he graduated with honours in zoology in 1948, and was awarded the degree of Ph.D. in 1951. From 1951 until 1956 he served as a research officer in the Department of Geology and Comparative Anatomy at the University of Oxford. During 1954–55 he held a Rockefeller fellowship and worked at Columbia University, New York. He was appointed a senior lecturer in genetics at the University of Liverpool in 1956 and a reader in 1959. Dr. Sheppard has served on the Committee of the Genetical Society of Great Britain and has worked extensively in the field of natural selection and heredity. He is especially interested in the genetics of butterflies and moths.

Signals Research and Development Establishment, Christchurch, Hants: Mr. R. J. Lees

Mr. R. J. Lees has been appointed director of the Signals Research and Development Establishment at Christchurch, Hants, in succession to Mr. R. V. Whelpton. Mr. Lees, who is at present head of the Instruments and Air Photography Division of the Royal Aircraft Establishment, was born in 1917. He joined the Telecommunications Research Establishment, Malvern (now the Royal Radar Establishment), in 1939, where he remained until moving to his present post at the Royal Aircraft Establishment in 1959. While at Malvern he was largely concerned with work on guided missiles, being superintendent of the guided weapons section in 1951. In 1953 he was appointed superintendent, experimental physics, in 1955 director of scientific research (guided weapons), and in 1956 head of airborne radar at the Royal Radar Establishment.

Ministry of Aviation Science Officers in Industry

In a written answer in the House of Commons on December 10, the Minister of Aviation, Mr. J. Amery, stated that in the past ten years applications to take up posts with industrial firms had been approved from one senior principal scientific officer, one principal scientific officer, four senior scientific officers, three senior experimental officers, two chemists and nine engineers. Mr. Amery emphasized that the Department employed several thousands of scientists, engineers and technical staff of potential value to industry, and that it had been the object of successive Ministers to ensure that, while industry was not denied the services of some very able people, nor they themselves the chance to make a new career, this fruitful exchange should not be allowed to influence the placing of contracts or to lead to favours being sought or given.

Grants for Education Research in Great Britain

In a written answer in the House of Commons on December 11, the Minister of Education, Sir Edward Boyle, listed grants totalling £183,000 for the financial year 1962–63 made or approved under the Educational Services and Research Regulations, 1946. Besides £58,000 over five years to the National Foundation for Educational Research for a study of the effects of streaming in primary schools and £21,000 over three years to the same Foundation, as well as £20,000 for a four-year study of the merits of block- and day-release, these include: £20,000 to the Brunel College of Technology for a five-year study of the learning of intellectually complex material; £13,000 to the Department of Education, Sheffield, for a three-year project on programmed learning; £15,000 to the Educational Foundation for Visual Aids for the audio–visual aids experimental development unit; £10,000 to the Department of Sociology, Manchester, for a four-year study of the effects of home life on school performance; £6,000 to the Department of Education, Birmingham (in association with the Department of English, Leeds), for a three-year project of oral English tests in the Certificate of Secondary Education; £5,000 to the Department of Education, Swansea, for a three-year study of teaching educationally sub-normal children. Grants totalling £46,800 for special education services include £14,500 to the Central Bureau for Educational Visits and Exchange,

£14,000 to the National Council for Diplomas in Art and Design, £6,500 to the National Council for Technological Awards, and £4,000 to the Field Studies Council.

British Space Research in 1961–62

British activities in space research in the year ending in May, 1962, are described in the *United Kingdom Report for 1961 to the I.C.S.U. Committee on Space Research* submitted by the British National Committee on Space Research to the fifth meeting of the Committee on Space Research in Washington during April 30–May 9 (Pp. 23. London: The Royal Society, 1962). The report gives a good summary of the varied investigations in progress, which are classified under the following headings: tracking and data recovery; atmospheric structure and composition; radio propagation and the ionosphere; geomagnetism; orbital analysis; micrometeorite studies; cosmic radiation; electromagnetic radiation and astronomy. There is also a selected list of more than seventy British papers published in late 1960 or 1961 on these and related subjects. The most striking event of the year under review, however, came at the very end, with the launching of the first Anglo-American satellite, *Ariel 1*, on April 26, and the booklet includes a photograph and cutaway drawings of *Ariel*. An appendix gives details of the experiments to be flown in the second Anglo-American satellite, which is to measure galactic noise, atmospheric ozone and the flux of micrometeorites.

Uniform Time and Constant Frequency for the Year 1963

Following the decision of the International Committee of Time at Berkeley, in August 1961, and the general assembly of the Union Radio Scientifique Internationale at London, in September 1960, and the Study Group VII of the Comité Consultatif International Télégraphique in Geneva, during April–May 1962, the International Bureau of Time consulted the observatories which have caesium atomic resonators with the view of comparing their astronomical observations. It has now calculated the nominal value of the frequency to transmit during the year 1963 as -130×10^{-10} with regard to the scale of time such that the frequency of caesium has the value: $f(\mathrm{Cs}) =$ 9,192,631,770 c/s. The value indicated will not change during the course of 1963. It is the same as the 1962 value. The International Committee of Time, the Union Radio Scientifique Internationale and Study Group VII of the Comité Consultatif International Télégraphique recommend that the value of the frequency indicated by the International Bureau of Time be utilized by the organizations desiring to transmit uniform time and constant frequency.

Personnel Management

An important development in the activities of the Institute of Personnel Management as shown in its annual report for 1961–62 is the increasing attention it is now giving to overseas contacts (Pp. 28. London: Institute of Personnel Management, 1962). Among the projects the Institute will undertake during 1963 to celebrate its jubilee is the foundation of a senior lectureship in industrial relations at University College, Ibadan, in Nigeria. The Institute already has about 600 overseas members, and during the past year the Institute's officers have visited several countries including India, Cyprus and Israel. Links with European personnel managers have been strengthened during the year, these having been stimulated by Britain's possible entry into the European Economic Community. European salary structures featured at the Institute's Conference in May, and labour relations in the European Economic Community were discussed at the South-West Regional Conference in April. At the end of June, a two-day meeting of chief personnel managers from West Germany and Britain was held in London and it is proposed to hold a similar meeting in Germany in 1963. In June a meeting was called by the Organization for European Co-operation and Development to discuss the formation of a European Personnel Management Group for liaison between different institutes and associations and for the exchange of information about personnel practices in the different countries.

Careers in Biochemistry

The Biochemical Society has published a revised version of the booklet *Careers in Biochemistry*. It starts by describing what biochemists do and the various types of laboratories in which they work. There are sections on educational qualifications and professional training, on opportunities and prospects, and on salaries. A short reading list is provided. This booklet should be very helpful to boys and girls considering taking up biochemistry and to those responsible for advising them. It is obtainable, price 2*s*. post free, from the Administrative Secretary, the Biochemical Society, 20 Park Crescent, London, W.1.

National Museum of Wales

For the first time in thirty years, extensions are being built for the National Museum of Wales, and a public appeal for at least £150,000 towards the cost has been launched. The Museum at Cardiff is less than half complete, and the present collections have outgrown the space available in which to exhibit them. Congestion is especially severe at the Welsh Folk Museum at St. Fagan's, and in the Welsh Museum's School Service. The building of the new wing has been authorized by the Government and the Treasury will meet 90 per cent of the cost. It is hoped that the appeal to the public will be successful—£91,697 was received before launching it.

Museum of Applied Arts and Sciences, Sydney

With a striking original design on the cover, the annual report of the Museum of Applied Arts and Sciences, Sydney, for the year ended December 31, 1961, is a record of much activity (Pp. 24. Sydney: Museum of Applied Arts and Sciences, 1962). The increased attendances are attributed to two main factors: first, a planned advertising programme; and secondly, that during the year under review special efforts were made to attract more organized parties from secondary schools. It was also in 1961 that Royal Assent was given to an Act which altered the name of the institution from Museum of Technology and Applied Science to Museum of Applied Arts and Sciences. Re-organization of the exhibition staff has permitted a greater degree of specialization according to special qualifications and talents. This has resulted in the formation of the nucleus of a design section, charged with the task of design in general as it affects museum activities of any kind and of co-ordinating the various contributory skills, for example, artist, ticket-writer, carpenter or painter. The chief event of the year in the exhibition galleries has been the re-display of the arms and armour collection.

Associated Electrical Industries' *Electron Microscopy*

Associated Electrical Industries' first scientific film, *Electron Microscopy*, which received four awards at the second International Industrial Film Festival in Turin in 1961, has now received the Nikola Tesler gold medal. This was the premier award at the third International Festival of Scientific and Technological Films in Belgrade, Yugoslavia. *Electron Microscopy* shows the principles, construction and operation of the electron microscope and the techniques of preparing specimens. A number of uses of the machine in research and industry is demonstrated, including the application of the image intensifier. The latest scientific film to be made by Associated Electrical Industries, *Analysis by Mass*, has been selected for showing at the annual meeting of the American Association for the Advancement of Science in Philadelphia at the end of December.

R331

U.S. Television 'Journal' for Science and Engineering

Scientific Information Notes for October–November 1962 (4, No. 5), issued by the National Science Foundation, notes that the Foundation is supporting an experiment in the use of television as a medium for communication from scientists to scientists. The experiment is being administered by the American Association for the Advancement of Science, and, with the co-operation of several scientific societies, is being developed as a television series to function as a 'journal' of science and engineering at professional level. The Foundation is also supporting a two-year study at Lehigh University, Pennsylvania, of methods of analysing the information needs and patterns of use of scientists.

Twentieth Anniversary of the First Nuclear Reactor

THE International Atomic Energy Agency has issued a special number of its *Bulletin* to mark the twentieth anniversary of the first nuclear reactor becoming critical on December 2, 1942. An introduction by the director-general of the Agency, Dr. A. S. Eklund, is followed by articles by L. Meitner on roads to the discovery of nuclear energy; Dr. O. Hahn, on E. Fermi and uranium fission; S. K. Allison, on initiation of the chain reaction; G. T. Seaborg, on the first nuclear reactor, the production and chemical extraction of plutonium ; Sir John Cockcroft, on the early days of the Canadian and British atomic energy projects; B. Goldschmidt, on France's contribution to the discovery of the chain reaction; V. S. Emelyanov, on the first atomic reactor in the U.S.S.R.; H. DeWolf Smyth, on the publication of the Smyth Report; E. P. Wigner, on the anniversary of the first reactor; J. A. Wheeler, on "Fission Then and Now"; G. de Hevesy, on the reactor and the production of isotopes; L. Fermi, on some personal reminiscences; C. Allerdic and E. R. Tragenell, on the first atomic pile.

William Dampier

A SHORT account ot the life of Dampier as explorer, seaman and scientist has been prepared by J. C. Shipman, of the University of Kansas (University of Kansas Publications, Library Series, No. 15: *William Dampier: Seaman-Scientist*. Pp. 63. Lawrence, Kansas: University of Kansas Libraries, 1962. 1.50 dollars). Shipman describes Dampier's voyages around the world, the many plants and animals attributed to him, as well as his many observations in oceanography. The book provides a valuable supplement to the larger existing works.

Anti-knock Efficiency of Methyl*cyclo*pentadiethyl Manganese Tricarbonyl

A. Girelli and C. Orlandi have studied the knock rating of methyl*cyclo*pentadiethyl manganese tricarbonyl (1), using that compound alone or in conjunction with tetraethyl lead (2), in eight normal production oil fuels from Italian refineries, each being of different chemical composition. The results of their investigations were given at the ninth National Congress of Chemistry, held in conjunction with the Swiss Chemical Society, at Naples, during May 27–June 2, 1962, and summarized in *La Rivista dei Combustibili* (16, 9; September 1962). Their findings are significant. With straight-run, paraffin-base petrol the octane number increases more with addition of (1) than of (2), giving the same concentration of grammes of metal per litre. Much the same is found in petrols produced by 'cracking' processes: for the same metal content the octane number rises more with (1) than (2). With increase of aromatic content in the distillates, however, the effect of additive (1) becomes less progressively compared with the more commonly used tetraethyl lead. Carrying the research a stage further, the authors tested the anti-knock behaviour of both (1) and (2) in combination added to the same series of petrols. They found that the synergic effect of this procedure was greatest in the paraffin-base petrols and decreased in proportion to rise in aromatic content. The chain of chemical reactions involved in these experiments is complex, but it is believed that the behaviour of (1) in the presence of (2) in the varying types of petrol used is due to the retarded action of (2) compared with (1). This can be explained by assuming that the reactive compound (1) in the form of manganese oxide precedes the influence of the lead oxide in (2) in the course of the combustion process. It is argued that, in consequence of this preference, the role of compound (1) is such that it breaks the chain of reactions ". . . which, in the presence of (2) alone, would continue undisturbed until knocking occurs before the appearance of the active form". These results apparently are in agreement with those of other workers on this problem and would seem to establish the fact that the anti-detonating efficiency of the manganese compound in light petroleum distillates, compared with tetraethyl lead, must now be reckoned with in modern refinery projects.

Gerontology in the United States

THREE brochures reviewing different aspects of research programmes in ageing conducted and supported by the National Institutes of Health during 1961 have been issued by the U.S. Public Health Service. The publications are prepared annually by the Centre for Ageing Research. *Research Highlights in Ageing* presents a review of a selected number of scientific papers on research in ageing, ranging from fundamental studies in the biology of ageing to studies concerned with the physical, psychological and social problems of ageing people (Publication No. 921. Pp. v+29. Washington, D.C.: Government Printing Office, 1962. 20 cents). *Activities of the National Institutes of Health in the Field of Gerontology* lists research and training grants either primarily or secondarily related to ageing (Publication No. 935. Pp. viii+47. Washington, D.C.: Government Printing Office, 1962. 35 cents). In each category the grants are classified under general headings and under such special groupings as physiological and biochemical aspects in ageing, psychological aspects, social aspects and disease processes. The third brochure, *Research Programmes in Ageing*, briefly summarizes the research programmes at the National Institutes of Health in this field as well as programmes at other institutions where the National Institutes of Health grants are sponsoring research in the increasing medical, social, economic, physiological and psychological problems associated with the ageing process (Publication No. 939. Pp. v+17. Washington. D.C.: Government Printing Office, 1962. 15 cents). Single copies of the pamphlets are available from the Centre for Ageing Research, National Institutes of Health. Bethesda 14, Maryland.

Animal Health Yearbook

THE *Animal Health Yearbook* is issued jointly by the Food and Agriculture Organization, United Nations, the World Health Organization and the International Epizootics Office, Paris. The 1961 issue provides tabulated statistical information concerning farm animals, including birds, in the countries which fall within the activities of these international bodies, this being the major portion of the text (Pp. 315. Rome: Food and Agriculture Organization, 1962. 15*s*.). There are brief accounts of five important laboratories which deal with matters that concern the disease problems of these countries in so far as they have, to that extent, application to their own countries (the Republic of South Africa, the United States and Britain). In addition, there is a brief account of the operations of the Inter-African Bureau of Animal Health in Kenya. This is a publication for the senior administrative office of a veterinary service, for veterinary libraries and other organizations interested in animal health, as well as for general workers in the interests covered by its contents. There is a mass of information about present-day affairs not available elsewhere as a whole within one book. In such a compendium the accuracy of figures may vary from country to country. The figures given could not be obtained elsewhere, except by laborious inquiry or search from a number, a very large number, of sources. To provide such a mass of information within a reasonable space, a very elaborate system of notation is used, this in itself requiring to be used when gleaning the data provided. There is an elaborate and useful index. The whole of the book is printed in three languages—English, French and Spanish.

Fertilization in Farm Animals

J. L. Hancock, of the Animal Breeding Organization, Edinburgh, has reviewed fertilization in farm animals (*Animal Breeding Abstracts*, 30, 285; 1962), and dealt with some 200 references of recent years. The text covers "Physiological Aspects of Fertilization" (duration of oestrus, time of ovulation, site of fertilization, time taken for spermatozoa to reach site of fertilization, numbers of spermatozoa at site of fertilization, functional life-span of spermatozoa in the female tract, functional life-span of the ovum, penetration of ova, morphological changes preceding and following fertilization, changes in unfertilized ova, criteria of fertilization, anomalies of fertilization), "Failure of Fertilization" (failure of sperm transport, defective gametes) and "Fertilization in Hormone-treated Females" (fertilization *in vitro* after ovum transfer, selective fertilization). Hancock emphasizes that basic information on the physiology of fertilization in animals is derived largely from studies of small laboratory animals.

Courses in Research and Development

The Comparative Administration Trust is organizing practical courses on "Administration and Management of Research and Development" in collaboration with Brooklands Technical College, Weybridge (January 14–February 8), Gonville and Caius College, Cambridge (July 14–August 9), Queen's College, Oxford (September 1–28), and Sundridge Park Management Centre, Bromley (November 10–December 7). The courses will be open to those with science or engineering degrees or equivalent qualifications, and are aimed at improving the practical effectiveness of those engaged in administration and management of technical work in industry, in industrial research associations or publicly sponsored research establishments. Forms of application and further information can be obtained from the Comparative Administration Trust, 30 St. George Street, Hanover Square, London, W.1.

Nato Advanced Study Institute on Palaeoclimates

An Advanced Study Institute on Palaeoclimates will be held under the auspices of the Northern Atlantic Treaty Organization's Science Office at King's College, Newcastle upon Tyne, during January 7–12. The programme has been divided into eleven sessions dealing with: the palaeoclimatic significance of coal; Cretaceous and Tertiary palaeobotany; palaeontology and palaeoecology; palaeontology; glaciation; Eo-Cambrian glaciation and Devonian climate; deserts and palaeowind aspects; evaporites; Permian climate; soils; meteorological aspects. The director of the Institute is Prof. S. K. Runcorn, head of the Physics Department, King's College. Further information can be obtained from the organizing secretary, Dr. A. E. M. Nairn, Nato Advanced Study Institute on Palaeoclimates, King's College, Newcastle upon Tyne.

The British Society of Acoustic Technology

Under the directions of committee of representatives from universities, local government, industry and the Royal College of Advanced Technology at Salford, and headed by Dr. L. H. A. Pilkington, of Messrs. Pilkingtno Bros., St. Helens, a Society of Acoustic Technology is to be formed. A programme has been prepared which includes both lectures and visits; topics which the Society will consider in the first half-session (beginning in January) include airport noise, psychological problems caused by excessive or particularly penetrating noise, measurement of noise-levels and the design of lightweight partitions intended to reduce noise. The inaugural meeting of the Society will be held on January 17 at the Royal College of Advanced Technology, Salford, when Prof. E. J. Richards, of the University of Southampton, will give an address on "Future Problems in Noise Abatement". The joint honorary secretaries of the Society are Dr. P. Lord, of the Department of Pure and Applied Physics, Royal College of Advanced Technology, Salford, and Dr. H. D. Parbrook, of the Sub-department of Acoustics, University of Liverpool. Further information concerning the inaugural meeting can be obtained from Dr. Lord.

Announcements

Sir John Wolfenden, vice-chancellor of the University of Reading, has been appointed to succeed Sir Keith Murray as chairman of the University Grants Committee. Sir Keith Murray will relinquish the post on September 30, by which time he will have served for ten years.

Dr. R. Franklyn Morris, of the Federal Department of Forestry, Fredericton, New Brunswick, has been awarded the first Gold Medal of the Entomological Society of Canada for his work in the field of insect population dynamics. Dr. Morris's work has provided a scientific basis for attempting the control of budworm.

M. S. Moss has been appointed to take charge of the Animal Health Trust's forensic laboratory at the Equine Research Station, Newmarket. Mr. Moss has been a member of the Metropolitan Police Laboratory, New Scotland Yard, where he has investigated the techniques of extraction and identification of drugs. The forensic laboratory at the Equine Research Station has been established to implement some of the recommendations contained in the report of the committee, under the chairmanship of the Duke of Norfolk, which inquired into the question of 'doping' of racehorses.

The British Association for Commercial and Industrial Education is organizing a special conference to consider the White Paper (Cmnd. 1892) *Industrial Training: Government Proposals*, which will be held at the Grand Council Chamber, Federation of British Industries, 21 Tothill Street, London, S.W.1, on January 15. Further information can be obtained from the Conference Secretary, BACIE, 26*a* Buckingham Palace Road, London. S.W.1.

A meeting of the Systematics Association on "The Place of Taxonomy in the Teaching of Biology" will be held in the Department of Botany, University of Birmingham, on January 26. Further information can be obtained from the Honorary Botanical Secretary, the Systematics Association, c/o British Museum (Natural History), Cromwell Road, London, S.W.7.

"The Role of Chemical Engineering in the Space Age" is the title of a lecture to be given by Prof. Ju Chin Chu, professor of chemical engineering at the Polytechnic Institute of Brooklyn, at the Geological Society, Burlington House, London, W.1, on January 28. The lecture is being organized by the Institute of Chemical Engineers, and further information can be obtained from the General Secretary of the Institute, 16 Belgrave Square, London, S.W.1.

GOVERNMENT SUPPORT FOR UNIVERSITIES AND COLLEGES IN GREAT BRITAIN

FOLLOWING last year's precedent, the University Grants Committee again prefaces its annual returns from universities and colleges in Great Britain in receipt of Treasury grants for the academic year 1960–61[*], now covering 22 universities and 3 colleges, with an introduction which in effect amounts to an interim report. This note refers to the establishment of an *ad hoc* advisory panel to deal with proposals for the development in the universities of studies in teaching English as a second or foreign language. Four universities have already initiated such studies and other universities have put forward proposals, but the rate of expansion is severely limited by the shortage of trained teachers and for the first years of the next quinquennium resources will be concentrated in the four universities where the studies are already established. Financial provision of £10,000 in 1962–63 rising to £70,000 in 1966–67 has been earmarked for these developments.

The University Grants Committee has also earmarked a sum of £560,000 in 1962–63, rising to £640,000 in 1966–67, for support of research projects from which the Research Councils are withdrawing support at the end of the current quinquennium but which the universities consider important enough to be given priority with, or immediately after, existing commitments ahead of any new developments. Following acceptance of the recommendations of the Hayter Committee on the further development of Oriental, Slavonic, East European and African Studies, involving expenditure rising from £120,000 in 1962–63 to £290,000 in 1966–67, an interim scheme for the award of special postgraduate scholarships to commence in October 1962 has already been adopted. Discussions are already proceeding with the universities on the further allocation of these funds and nine centres for area studies have already been selected. Fourthly, the Committee has earmarked special funds, rising from £185,000 in 1962–63 to £750,000 in 1966–67, for the development of dental schools, both for teaching and research. This will permit the intake of dental students being raised, as requested by the Government, from 620 to 940 a year.

The University Grants Committee is also discussing with the universities the meeting of two other national needs brought to its notice. First, the Government requested the Committee to consider the possibility of increasing the intake of the medical schools by 10 per cent above the level recommended by the Willink Committee and in the initial discussions it was assumed that the recurrent grants for 1962–67 would allow for a reasonable development of the medical schools. Following the Government's rejection in March of the Committee's recommendations for recurrent grants during that quinquennium, further advice was submitted to the Government in July. The new recommendations were accepted by the Government, and, in addition to capital grants of about £100,000, recurrent grants for this purpose, rising from £135,000 in 1962–63 to £245,000 in 1966–67, will be provided.

The second matter was raised by the Foreign Office late in the year and relates to the further development of Latin-American studies, and a committee, with Dr. J. H. Parry as chairman, has been set up to review developments in the universities in the field of Latin-American studies and to consider and advise on proposals for future developments. The University Grants Committee also notes that, while the proposals originally put forward by the universities provided for the 500 additional places in University Departments of Education requested by the Ministry of Education for the next quinquennium, the funds made available under the Government's announcement last March fall short of the universities' and the Committee's estimates of their needs. While the Committee makes no direct comment on this decision, it does not conceal its concern at the probable consequences of the decision on standards of teaching and research in the universities or on the ability of the universities to provide the number of student places desired by the Government. There will clearly be little money available for other developments during the quinquennium and, small as are the earmarked grants already mentioned, against this background the risk of distortion is greater.

Assessment of the universities' recurrent financial needs during the coming quinquennium was indeed the Committee's main concern during the year. In this connexion it points out that net expenditure on existing commitments is bound to increase, particularly in respect of salaries and building programmes, and it concludes that to meet existing commitments the universities as a whole would need a 3·5 per cent increase in grants over 1961–62 in 1962–63 and 15·9 per cent in 1966–67. The Committee's proposals contemplate provision of places for 151,000 students by the end of the quinquennium, an increase of 36 per cent over 1961. The calculations on which the Committee's report to the Chancellor of the Exchequer on the 1962–65 building programme was based showed that if standards of admission were not raised, by 1966–67 at least, 180,000 if not 200,000 places might be required for those academically qualified. Of the 30 per cent increase to 144,500 students (compared with 111,100 in 1961–62) about two-thirds will take place in the pure and applied sciences. The respective percentages are: pure science, 41·7; applied science, 60·4; medicine, 8·4; dentistry, 35·2; agriculture and forestry, 20·9; veterinary science, 13·7.

For the rest, this general survey notes the establishment of a small *ad hoc* group to consider in principle and advise on the advantages which can be secured from a proposed grouping of postgraduate institutes and hospitals and their joint use of facilities. Furthermore, in view of the National Coal Board's intention to reduce considerably its demand for graduates in coal-mining and to concentrate its assistance to university mining departments on five instead of nine, the University Grants Committee is participating in relevant discussions to effect this concentration without hardship to academic staff or students concerned. The Board wishes to concentrate its help in the mining departments of King's College, Newcastle upon Tyne, the University College of South Wales and Monmouthshire, the University of Nottingham, either the University of Leeds or the University of Sheffield, and in one centre in Scotland. The question of academic salaries is discussed at some length (this and other financial matters are considered on p. 1 of this issue of *Nature*).

The number of full-time students in British universities increased to 107,699, compared with 104,009 in 1959–60, and of these 17,925 were in the Universities of Oxford and Cambridge, 21,995 in the University of London, 42,819 in other English universities, 6,431 in the University of Wales, and 18,529 in Scottish universities. There were 11,608 students from overseas, 6,932 of whom were from within the Commonwealth, and 5,242 of whom were postgraduate. Of the full-time students 27·4 per cent were in colleges or halls of residence, 50·7 per cent in lodgings and 21·9 per cent at home; these figures compare with 28·1, 40·9 and 31·0 per cent, respectively, in 1953–54; these proportions varied widely in different universities and for men and women. In Scotland only 9·6 per cent of men and 20·0 per cent of women were in colleges or halls of residence, while 50·7 per cent of men and 45·4 per cent of women were at home.

---

[*] University Grants Committee. Returns from Universities and University Colleges in receipt of Treasury Grants, Academic Year 1960–61. (Cmnd. 1855.) Pp. xxiv+48. (London: H.M. Stationery Office, 1962.) 5s. 6d. net.

Of full-time men students 25·4 per cent were in arts and 11·5 per cent in social studies; 25·5 per cent in science, 19·5 per cent in technology and 11·5 per cent in medicine; for women the corresponding figures are: 52·7; 9·4; 21·7; 1·3; and 11·2. Of those that were 'full-time', and apart from students engaged in research or other advanced work, 27,702 were in arts, 10,115 in social studies, 21,395 in pure science, 13,597 in technology and 11,199 in medicine. Among the 17,836 advanced students, 3,551 (2,193 men) were taking postgraduate courses in teacher training; 3,326 of the others were in arts, 1,692 in social studies, 5,058 in pure science, 2,628 in technology, and 1,077 in medicine. Of full-time students 84,999 were reading for a first degree, 3,958 for a first diploma and 908 attending courses not leading to a degree or diploma; the proportion of men (75·5 per cent) and women (24·5 per cent) was again little changed from 1938–39 (76·7 and 23·3 per cent, respectively). Of the 29,510 full-time students admitted for the first time in 1960–61, 32·7 per cent were in arts, 12·0 per cent in social studies, 26·4 per cent in pure science, 15·1 per cent in technology and 8·8 per cent in medicine, and over the past four years increases in pure science and technology have been about twice as great as in arts.

The proportion of assisted students was 82·4 per cent, as in 1959–60, which compared with 71·9 per cent in 1953–54, ranging from 92·6 per cent in Wales, 89·2 in English universities excluding those at Oxford, Cambridge and London, to 72·8 per cent for Scotland. There were 17,831 part-time students, 4,860 from overseas, and of these 13,478 were in English and 4,132 in Scottish institutions; 6,234 were engaged in research or other advanced work. Full-time teaching and research staff, excluding Oxford and Cambridge, increased to 12,105 (11,474 in 1959–60) and 25·7 per cent are now in science, 14·8 per cent in technology and 17·4 per cent in medicine. The percentage of professors was 12·0, readers and independent lecturers 6·2, senior lecturers 12·3, and lecturers 47·7. Including Oxford and Cambridge the grand total was 12,417.

Of the recurrent increase of £68,706,388 (£59,800,092 in 1959–60), £48,399,076 (70·4 per cent) was from Treasury grants, and £1,224,802 from grants from Government departments; £6,317,603 from fees (9·2 per cent), £1,963,347 (2·9 per cent) from endowments, £1,577,564 (2·3 per cent) from local authority grants, £506,806 from donations and subscriptions, and £6,215,400 (9·1 per cent) from payments for research. It is expected that the increase in students' fees will provide a further £1·3 million or 1·7 per cent of total income in 1962–63. For English, Welsh and Scottish Institutions the totals are £55,506,730, £3,437,275 and £9,762,383, respectively. Non-recurrent Treasury grants amounted to £22,199,128, an increase of £2,346,381 over the previous year, and of this £14,576,504 was spent on building work, £2,212,152 on professional fees, £4,123,907 on furniture and equipment and £1,286,565 on site and property purchases. Of the recurrent expenditure of £67,822,988—an increase of £9,317,916 on 1959–60—6·7 per cent was spent on administration, 44·1 per cent on salaries and superannuation of teaching staff, 11·2 per cent on departmental wages, 14·1 per cent on departmental and laboratory maintenance, 3·3 per cent on repairs and maintenance of buildings and 9·8 per cent on rates, insurance, heat, light, etc. Expenditure on libraries, at £2,624,625, fell slightly to 3·9 per cent of the total.

SCIENTIFIC RESEARCH IN NEW ZEALAND

THE report of the Department of Scientific and Industrial Research, New Zealand, for the year ended March 31, 1962, includes the Minister's Statement, the report of the Council and the Secretary's report, as well as reports from the various Divisions of the Department, the incorporated Research Associations and on grant-aided research in the Cawthron Institute, Lincoln College, Massey College and the Industrial Development Department of the University of Canterbury*. Lists of publications during the year are appended to these reports and to the whole is appended the fourth annual report of the Ross Dependency Research Committee. The latter records reconnaissance geological and mapping surveys of 27,000 square miles in the Beardmore Glacier region, a unique study of temperature gradients in Lake Vanda in the Wright valley, and a new study of penguins, seals and marine biological problems in the McMurdo Sound area.

The Council's report records the adoption by the Government of the Council's proposals for changes in the basis of support by State Departments of research in the universities. Under these, State Departments will sponsor and provide funds for research units in the universities in fields of study deemed essential in the national interest and in which an outstanding man is available in the university, enter into research contracts with the universities for specific research projects, and provide studentships in fields of science of special interest to the department concerned. Meanwhile, the Department of Scientific and Industrial Research will provide funds for the establishment in 1962 of research units in agricultural economics at Lincoln College and in molecular biology at the University of Auckland. The Council has also considered strengthening the Auckland Industrial Development Laboratories and re-equipping the workshops of the Dominion Physical Laboratory and is negotiating with the University of Canterbury on the future work of its Industrial Development Department.

Of the total vote of £2,192,000 in 1961–62, £225,000 was spent on grants to other organizations. The total compares with an average of £1,895,000 over the three years 1958–61, which represented 0·149 per cent of the gross national product, compared with 0·134 per cent in 1955–58 and 0·154 per cent in 1949–52. The total staff on March 31, 1961, of 1,148, including 422 scientific officers, increased to 1,170 by the end of the year, including 442 scientific officers. The Council comments on the inadequacy of the amount of capital available for renewal and purchase of scientific equipment and on the demand for research into an ever-increasing number of fields. Grants to research associations in 1961–62 totalled £147,850, and to Canterbury and Massey Agricultural Colleges and the Industrial Development Department, University of Canterbury, £24,149, while the Commonwealth Agricultural Bureaux received £18,680 and the Cawthron Institute £12,400.

Commenting on the economic value of the Department's research work, the Secretary in his report refers to the importance of the work done on the control of bloat in dairy cattle for which a cheap and efficient method has been found by spraying peanut oil and tallow on the pasture. The discovery by the Entomology Division that small amounts of DDT give effective control of the grass grub has resulted in it being kept well under control in most parts of the country; as a pest, the grass grub has previously cost New Zealand some £6 million a year. Damage done by the white butterfly and the diamond black moth has been reduced to a low level by the introduction of their natural predators, and a safe and effective hormone–fungicide spray has been developed for control of grey mould or botrytis on tomatoes, while acceptable methods of spray application of diphenylamine have been developed which are expected to reduce scald of apples in storage to negligible proportions. Savings in thinning costs of Statesman apples, estimated at £20,000 a year, have been obtained by the introduction of hormone sprays, and the short-rotation rye-grass developed by the Grasslands Division is now valued at £150,000 a year in seed alone, while Savoy cabbage strains bred by the Crop Research Division are yielding about 2·5 tons per acre more than the best commercial strains and are superior in uniformity and time of maturity. Between 1948 and 1960 the yield of tobacco leaf per acre was raised from 789 to 1,856 lb. with a simultaneous improvement in quality, and the study of curing conditions in the kiln has led to the use of a down-draught kiln which gives more uniform curing, reduces fuel consumption by one-third and drying time by 24 h.

---

* New Zealand. Report of the Department of Scientific and Industrial Research for the year ended 31 March, 1962. Pp. 87. (Wellington: Government Printer, 1962.) (H.34.)

The Secretary's report also mentions the Soil Bureau's discovery of the importance of molybdenum as well as fluorine in connexion with dental caries, which could have a profound effect on the condition of children's teeth. Of the present research work, the report notes that the study of foraminifera is well advanced in New Zealand and that the Geological Survey's palynologists were called on to examine fossil pollen samples from coal-bearing strata penetrated by the drills. Field trials have shown that the high-temperature Geiger tubes developed within the Institute of Nuclear Sciences can operate for long periods in the geothermal bores at Wairakei and that the counters can detect small differences in the radioactivity of the rocks and aid the correlation of the geological strata from hole to hole. A design procedure that permits an estimate of the safety of any proposed building and its occupants if subjected to earthquake has now been developed to an intermediate stage and results of the study of a number of standard buildings have been issued in a handbook. A method has been devised to assist the diagnosis of heart defects consisting of an abnormal connexion between the chambers of the right and left sides of the heart in which a sample of dye is rapidly injected into the blood stream at a selected site and afterwards detected downstream from the injection. A detailed study of clay fractions from different horizons of 54 soils has been made with the electron microscope and by chemical and mineralogical analysis. Reported sulphur deficiencies in New Zealand soils appear to be confined to soils with a very low absorbed sulphate content and a low absorption capacity, so that added sulphate is not retained in competition with phosphate, and when the two anions are added together, as in superphosphate, the sulphate is rapidly leached from the soil. Work on oestrogenic substances in red and subterranean clover has confirmed that the activity of red clover can affect the reproductivity of grazing cows and has provided a basis for investigating the heritability of oestrogens in clover progenies. Bitter pit in Cox's Orange and Golden Delicious apples has been reduced by calcium nitrate sprays.

NOMENCLATURE OF ISOLATES OF VIRUS FROM TRACHOMA AND INCLUSION BLENNORRHEA

At an informal meeting following the New York Academy of Sciences symposium on "Biology of the Trachoma Agent" in May 1961, an *ad hoc* committee was formed to try to establish a uniform system of nomenclature for trachoma virus isolations. The various institutions represented by the committee members are: Prof. J. H. S. Gear, the South African Institute for Medical Research, Johannesburg; Dr. F. B. Gordon, Naval Medical Research Institute, Bethesda 14, Maryland; B. R. Jones, Institute of Ophthalmology, London, W.C.1; Dr. S. D. Bell, jun., Harvard University School of Public Health, Boston 15, Massachusetts (chairman of the committee).

At the eighth International Congress of Microbiology, held during August 1962, the committee presented the views of the majority of persons interested enough to communicate their thoughts on the subject. The final recommendations which were voted by those present at Montreal followed the system proposed by Dr. Leslie Collier in almost all respects The elements are as follows:

(*a*) (*b*) (*c*) (*d*) (*e*)
TRIC/antigenic group/country or State/number/origin

(*a*) The term *TRIC* refers to the trachoma-inclusion conjunctivitis group of viruses.

(*b*) This space would be left blank or can be filled in when this information is available.

(*c*) The country or state from which this specimen was obtained is to be designated by the internationally recognized automobile plate letters, with such further geographic designation as is necessary for clarity.

(*d*) If this system can be administered by a central agency such as the World Health Organization, sequential numbering following the country of origin is favoured. If no central agency is available, it was thought best to insert a laboratory designation before the number.

(*e*) The origin of the clinical material would be inserted here as follows with the *O* or *G* optionally followed by a *T*, *C* or *N*: *O* = from the eye, *G* = from the genital tract, *T* = diagnosis of trachoma, *C* = diagnosis of conjunctivitis, *N* = diagnosis of ophthalmia neonatorum.

The full designation of the *G*–1 strain[1] therefore would be: *TRIC*/ /*WAG*/*MRC*–1/*OT*. *WAG* = West Africa Gambia, *MRC* = Medical Research Council.

Similarly the nomenclature for the *SA*–2 strain[2] assuming acceptance of the immunological groups proposed at present would be: *TRIC*/2/*SAU*/*HAR*–2/*OT*, *SAU* = Saudi Arabia, *HAR* = Harvard, and the strain of inclusion conjunctivitis[3] now called *IC*–*Cal*–1 would be: *TRIC*/ /*USA*–*Cal*/*Cal*–1/*ON*.

Whether or not strains already isolated should be incorporated into this system is left to the individual laboratories concerned, but the *ad hoc* committee feels that in the interests of uniformity and ease of communication, it is desirable that all new isolates should be officially designated by the above system as from January 1, 1963, onward.

INFORMATION IN BIOLOGY

An international colloquium on information in biology was recently held at Royaumont, near Paris. The aim of the organizing committee was to bring together workers interested in various fields of biology in which problems of information are faced—genetics, biochemistry, immunology, embryology, neurophysiology. Certain sessions were devoted to reports covering a broad field, followed by a general discussion; others were seminars with brief reports and original contributions on a limited subject. The discussions used to continue around the luncheon table, in the cloister or in the gardens of the Abbey. The value of such a meeting resides as much in these conversations, in improvised discussions and remarks, as in the prepared reports and contributions themselves.

M. Delbrück was chairman of the seminar on genetic information which occupied the first half of the colloquium. It is only one year since Nirenberg reported the specific stimulation by synthetic polynucleotides of amino-acid incorporation into protein material and an almost complete amino-acid code has already been proposed. Nirenberg and Lengyel both reported experiments which led to assigning one or more nucleotide triplets to each amino-acid; there is good agreement between most results of the two laboratories. The genetic code, however, is not yet completely solved; many questions and some difficulties remain. M. Bretscher directed the attention to two sources of error: in many of the experiments from which the present tentative code was derived the composition of the synthetic polynucleotide was assumed to be the same as that of the mixture of nucleoside diphosphates used to make them. According to M. Bretscher and M. Grunberg-Manago, this assumption is not warranted, and in many cases therefore the calculated frequencies of triplets on which the code rests might be wrong. The assumption that phenylalanine is coded by *UUU* exclusively is also uncertain and the triplet assignments rest on this assumption. Nirenberg reported that most of the polynucleotide added to the *E. coli* preparation is destroyed within a few minutes; a small part only, which is bound to the ribosomes, remains and acts as the template. It is not certain whether all the polynucleotides have equal chances of being bound. The presence of *U* in all the proposed coding units is not what one would expect, for no known nucleic acid is as rich in *U* or *T* as would be a template corresponding to the proposed code. According to the Cambridge–Paris group, poly-*A*–*C*, free of *U*, does stimulate the incorporation of three amino-acids, indicating the existence of codons (a word proposed by Crick for coding sequences) which do not contain any uracil. The proper interaction of polynucleotides with the ribosomes may depend on the solubility or the secondary structure, and *U*-containing polynucleotides might have an advantage over the others in this respect when assayed in the Nirenberg system.

The present code is but a first approximation: after these discussions, one would even doubt its significance, if it were not for the striking agreement between the code as it stands and many of the replacements of amino-acids observed in mutants. That Nirenberg's system can indeed make defined proteins when a natural RNA is provided to it, is shown by experiments from Fraenkel-Conrat's laboratory. Isolated tobacco mosaic virus RNA added to Nirenberg's system stimulates the incorporation of amino-acids into protein material which can be precipitated with an antivirus serum. A fraction of this material closely resembles the coat protein of tobacco mosaic virus; by hydrolysis, it gives apparently the same peptides. This fraction, however, is not perfect coat protein, for it does not aggregate into rods as does the real tobacco mosaic virus protein, possibly because the acetylation of the NH_2 end of the polypeptide fails to occur in *E. coli* extracts.

Incidentally, tobacco mosaic virus RNA causes the synthesis of other polypeptides besides that which resembles the coat protein, for the RNA stimulates the incorporation into protein material of two amino-acids which are not found in the coat protein. It is indeed most probable that tobacco mosaic virus RNA, like phage DNA, also codes for enzymes required for virus multiplication, and not only for the protein sheath of the virus. The previously established fact that many tobacco mosaic virus mutants have no amino-acid replacements in their coat protein already indicates that only part of the RNA molecule codes for the virus protein and that the rest of the RNA nevertheless is important for the process of virus infection.

Wittmann reported on further investigations concerning the amino-acid replacements obtained in nitrite mutants of tobacco mosaic virus. A given amino-acid is replaced by a very restricted choice of other amino-acids only, indicating that the number of meaningful substitutions within a codon is small. Since the replacement of an amino-acid does not lead to the replacement of its neighbours, the coding units are largely independent—the code is probably non-overlapping: but it is degenerate, for part of the amino-acids are coded by more than one triplet. If one assumes that de-amination results in the replacement of *C* by *U* and of *A* by *G* (*H* pairs like *G* and is ultimately replaced by *G*), the 64 possible triplets can be ranged in 8 groups of filiation; within each group, each triplet is related to three others by a one-step mutation obtainable by de-amination.

It is striking that all the transitions so far observed fall into three of the eight possible filiation groups. Unless some restriction to the observable transitions is imposed by factors irrelevant to the code, Wittmann's results suggest that the degeneracy of the code might obey certain rules. An interesting proposal for a logically degenerate code was presented by Woese on theoretical grounds. It is assumed that the three bases in each codon do not carry the same amount of information. In one of the positions, the four bases are recognized as different, but in the other two positions, only the nature of the group (NH_2 or OH), either in position 2 or in position 6 of the heterocyclic ring, is read. This is a degenerate code since in the member which codes according to its position 6, *U* is equivalent to *G* and *C* to *A*, and in the member which codes for ring positions 2, *C* is equivalent to *U*. Such a code would account for the wide differences in DNA composition of different micro-organisms without much change in protein composition, and also for the high *U* content of the codons derived from Nirenberg's system, since in one of the three members of the triplet *U* would have the same meaning as *G* and in another member *U* would be equivalent to *C*. Woese's code fits rather well with the coding assignments of the *E. coli* system, and with existing replacement data. In an excellent discussion, F. Crick analysed the present state of the coding problem, concluding that the genetic code is probably universal, partly degenerate, that there is little, if any, overlapping of the codons, and that the codons may indeed be made of three nucleotides.

The information coded in the template is read by transfer RNA. This is clearly proved by works done by F. Chapeville in F. Lipmann's group: cysteine bound to its specific transfer RNA was chemically changed into either alanine or cysteic acid and the resulting product assayed for its transfer properties in a *E. coli* system programmed by poly-*UG* which normally stimulates cysteine incorporation. The modified amino-acids when bound to cystein transfer RNA behaved like cysteine, showing that the positioning of an amino-acid on the template does not depend on the amino-acid itself, and that it is determined exclusively by the properties of the transfer RNA to which it is bound. By fractionating transfer RNA's from *E. coli*, Sueoka showed the existence of more than one transfer RNA for certain amino-acids, for example, two each for Leu, Ser, Try, Asp, Glu, three for Ile. Moreover, results from S. Benzer's laboratory show that the two separable transfer RNA's specific for Leu must carry different reading sequences since one of them transfers Leu to *UC* polymers only, the other one to *UG*, not to *UC*; therefore, the two transfer RNA's which read leucine are not interchangeable. The concept of degeneracy will have to be reconsidered in the light of such experiments: the code is degenerate in this sense that one amino-acid can be coded by more than one codon, but if these different codons are nevertheless recognized as different by the reading system, the code is not degenerate in the same sense as Woese's code. Plurality, rather than degeneracy, is indicated by these results. It will be interesting to know whether the different leucine residues of the same protein are coded by the same word or whether certain positions are coded in one language and others in the other.

Certain mutants can be restored to an almost wild phenotype by mutations occurring far from the structural gene in which the original mutation occurred. Genetic studies on these 'suppressor' mutations provide extremely interesting data on the reading mechanism. An example was presented by A. Garen, who studied mutants of the alkaline phosphatase cistron, which do not produce any cross-reacting material, and therefore possibly do not produce any protein in place of the phosphatase in the locus of which mutations occurred. It is assumed that the mutation in the phosphatase locus changes a codon into a nonsense triplet, with the result of blocking the synthesis of the phosphatase polypeptide. The synthesis of active enzyme with normal immunological properties can be restored by a 'suppressor' mutation. This second mutation probably changes the structure of a transfer RNA in such a way that this RNA now reads the nonsense triplet as if it was a good codon. The function of the normal transfer RNA which was changed by the mutation cannot be lost, otherwise the mutation would be lethal; on the other hand, the change in reading specificity should not cause too much damage to the other proteins; there are several escapes to these difficulties. A misreading, anyway, is better than no reading at all, and this might justify the existence of several codons for the same amino-acid: the more there are of meaningful codons, the smaller are the chances for a mutation to produce a nonsense triplet (cf. Benzer).

As an introduction to the next section of the discussion, F. Jacob briefly outlined the problem of transfer of information from the gene to the machine which makes proteins; he summarized his theory of information transfer and regulation and emphasized the support it receives from current works on short-lived RNA's and on the Nirenberg system. Jacob then raised a few questions which introduced the next papers: Do rapidly labelled RNA's carry genetic information? What are the biochemical and physical properties of messenger RNA? At what level does regulation operate?

Rapidly labelled RNA now appears very heterogeneous in size. It is quite reasonable to assume that large messengers carry the message for long polypeptides. By combining chromatography and density gradient centrifugation, R. Monier was able to resolve rapidly labelled RNA into several components. Certain fractions have a sedimentation constant as high as $30S$; this corresponds to rather big RNA molecules, larger than those of ribosomal RNA, and large enough to code for several proteins. One wonders whether messages for several proteins can be delivered as a unit to the ribosomal machine, whether some messenger RNA's contain the information of a complete operon. F. Gros showed that the activity of various RNA fractions when assayed in Nirenberg's system depends essentially on their content in rapidly labelled RNA. Free ribosomal RNA is inert; it is not even attached to ribosomes. Another question is whether each molecule of messenger RNA is able to direct the synthesis of only one copy of a polypeptide or whether it is used over and over again. The differential effects of inhibitors on the synthesis of proteins and of messenger RNA in bacteria indicate that each molecule of messenger RNA can function several times, perhaps 10 or 20 times before losing its activity.

Evidence that the different genes of T_2 bacteriophage send their messages at different times after infection was presented by two independent groups (R. Hessin and S. Spiegelman). Short pulses of tracer were given at various times after infection, the labelled complementary RNA was isolated by hybridization with phage DNA; the RNA's which are produced at various times after infection do not compete for the DNA, indicating that they correspond to different regions of the DNA molecule.

Another investigation by S. Spiegelman concerns the fate of the infecting RNA of a small RNA bacteriophage. Phage RNA binds to the $80S$ particles and stays there for a long time without being degraded. The association between this RNA and the ribosomes is very stable even at low magnesium concentration. This is in sharp contrast with what happens when the same virus RNA and ribosomes are confronted *in vitro*; association depends on high magnesium concentration, a large part of the RNA is destroyed during incubation and lowering the magnesium concentration results both in the separation of virus RNA from ribosomes and in the dissociation of the ribosomes themselves. Spiegelman also reported that this phage RNA causes the labelling of two proteins in the *E. coli* system. One of them is the coat protein; the function of the other one is not known.

The series of lectures on information in protein synthesis was closed by a report by M. Beljanski. In a soluble preparation from *A. faecalis* amino-acids bind to RNA's isolated from ribosomes; the binding depends on the presence of nucleoside triphosphates; analogues of purines or pyrimidines interfere with this fixation. Under certain conditions, rather large free peptides are formed.

M. Cohn very clearly summarized basic facts of immunological response, the intricate problems they raise and the current theories, of which he considered only the genetic models. The specificity is assumed to reside in the genetic material, the antigen regulating the production of a specific antibody or selecting the antibody producing system among the many existing potentialities. M. Cohn then summarized present knowledge on the structure of γ-globulin as deduced from immunological, chemical and genetic studies. The structural basis of antibody activity was discussed by R. Porter; his approach may answer the fundamental question as to whether the specificity of antibodies rests on differences in amino-acid sequence. Rabbit γ-globulins appear to be made of two identical *A* chains, flanked by two smaller *B* chains. Papain splits the antibody into three fragments: one of them, which was crystallized, is made of a rather large piece of the double *A* chain; it does not carry specific combining sites. The other two are probably identical to each other, each containing one of the two combining sites; they are formed of a *B* chain associated with the remnant of an *A* chain. The *B* chain was isolated; by itself it does not possess binding specificity. The fragment of *A* associated with *B* could not be studied easily because of a tendency to aggregate at neutral *p*H but such activity as survived the separation was always in the *A* chain. Comparable studies by G. Edelman and B. Benacerraf on guinea pig antibodies indicate differences in electrophoretic mobility between the *B* chains of different antibodies; it would seem that *B* may take part in the specificity although it does not bind antigen when separated from *A*. The combining site appears to be in the *A* chain remnant, but it may be formed by the association of *B* with part of *A*.

The amount of work presented and discussed at Royaumont was so great that when the programme was half way through, it was realized that there was not enough time left for the second half. It was agreed that the discussion on information in embryology would be replaced by two brief talks meant to state the problems and present perspectives. Thus C. H. Waddington considered essential problems of embryonic differentiation in terms of the mechanisms which control the synthesis of specific proteins. Experiments on nuclear transplantation and other less-direct evidence indicate that differentiation does not necessarily depend on permanent genetic changes; differentiation must involve switching on or off whole batteries of genes. Obvious questions occur: how are genes co-ordinated? How rigid is this co-ordination? What is the nature of 'genotropic substances', that is, of cytoplasmic substances which must control the activity of the genes? For if the cytoplasm in bacterial systems appears ancillary in regard of the all-mighty genome, embryologists view the cells and embryos as a much more involved system in which the cytoplasm exerts a very strong control on the genome.

Reasons why embryologists give a great importance to the cytoplasm were also illustrated by J. Brachet, who summarized fundamental facts about the early determinism of morphogenesis during cleavage. During this period of development, DNA replicates whereas protein and RNA synthesis are non-existent. Ribosomes isolated from eggs at this stage nevertheless incorporate amino-acids *in vitro*; the inactivity of ribosomes *in vivo* at that stage thus raises a clear problem of regulation. Hybrids between different species offer a means of studying the specific interactions between a genome and a foreign cytoplasm. Thus hybrids between frog and toad show a normal cleavage but are blocked precisely at the stage when specific protein synthesis normally begins. RNA metabolism in many nuclei of such hybrids is disturbed.

After this glimpse over challenging problems facing the molecular biologist of to-morrow, the symposium turned to considerations on enzyme structure and function, which were introduced by a brief report by R. Wurmser. The information content of an enzyme can be looked at from different points of view. Considering only the specificity of enzymes toward substrates, one obtains a small amount of information; but if one considers the actual support of enzyme activity, the protein itself, and calculates the amount of information from the negentropy of such a structure as estimated from the possible permutations of the amino-acids, figures of the order of several thousand bits are obtained. The reports and discussions which followed showed indeed that many structural features of the protein are important for enzymatic activity.

B. Keil raised the question as to whether the arrangements of amino-acids in protein chains obey certain rules. Common themes in amino-acid vicinity are obviously connected with function: thus the presence of aspartic acid close to the reactive serine is a common feature of esterases. Analogies of sequences between enzymes of similar function can also be recognized in the rest of the molecule, although this requires much more faith or enthusiasm. The notion of an active centre comprised of a few chemical groups is too narrow and altogether inadequate; the catalytic properties of an enzyme indeed depend on the rest of the protein as well —they can be altered by subtle changes occurring in other parts of the protein. Activation of trypsinogen and of chymotrypsinogen are good examples. Here the active centre is created by a transition of the secondary and tertiary structures made possible by the rupture of one peptide bond. P. Desnuelle gave another example: lipases which are active on insoluble substrates only, as if adsorption at the interface would cause a structural change necessary for enzymatic activity to appear. J. Yon discussed factors from which the activity of trypsin may depend. A fragment of the trypsin molecule containing less than one-third of the polypeptide chain can be isolated by pepsin treatment. It is enzymatically active, but its specificity is not as restricted as that of intact trypsin; it can hydrolyse substrates of chymotrypsin, beside those of trypsin. On the other hand, the specificity of trypsin becomes narrower in the presence of copper ions: activity on lysyl linkages is increased, whereas hydrolysis of arginyl linkages is inhibited.

Another example was given by F. Labeyrie. Mild treatments may change the properties of a yeast lactic dehydrogenase: the enzyme which has been crystallized does not have the same affinity for a competitive inhibitor, D-lactate, as the native enzyme. A very striking type of enzyme modification was discussed by G. Tomkins. A glutamic dehydrogenase with a molecular weight in the range of one million can dissociate under various conditions into four molecules which have lost the ability of oxydizing glutamic acid, but which now possess all the properties of an alanine dehydrogenase. The type of chemical reaction catalysed is the same; but the substrate specificity of the enzyme depends on its state of aggregation. Extracts of HeLa cells contain alanine dehydrogenase, but no glutamic dehydrogenase. Addition of ADP causes the aggregation of alanine dehydrogenase into glutamic dehydrogenase. ADP in this case is not a metabolite, it acts physically, causing association; it is a kind of 'configurational co-factor'. Certain steroid hormones, on the contrary, split glutamic dehydrogenase into alanine dehydrogenase. These and similar processes suggest new mechanisms for the regulation of enzyme activity.

Delicate interactions between proteins or regions of proteins are also illustrated by complex enzymes. C. Gunsalus discussed the stereospecificity of dehydrogenases involved in the metabolism of camphor, the co-operation of two enzymes in a process of lactonization and the induction specificity of these enzymes. E. Racker described the case of glyceraldehyde dehydrogenase, a double-headed enzyme which catalyses two successive reactions; the oxidation of the aldehyde by DPN with the formation of the acylenzyme, and the phosphorolysis of the acylenzyme with formation of free acylphosphate. Chymotrypsin splits the dehydrogenase releasing a smaller protein which still catalyses the first reaction, but has lost the phosphorolysis activity. Erythrose diphosphate inhibits the first reaction in the native enzyme; but it has no effect on the split enzyme; binding of this inhibitor depends on a part of the protein which does not contain the active centre. Negative feed-back, that is, the process by which the end-product of a metabolic chain inhibits the enzyme which catalyses the first step in that particular chain probably rests on effects of a comparable type. G. Cohen gave a few examples of feed-back regulatory processes, with emphasis on branched metabolic chains. The kinetics of inhibition of the controlled enzymes is not quite of the competitive type; the structure of the inhibitor is indeed very different from that of the substrate of the enzyme, hence the suggestion to name this type of process 'allosteric inhibition'. The sensitivity of enzymes to allosteric inhibition is often a very labile feature of the enzyme protein; it can be abolished without impairment of the catalytic activity of the enzyme. Beside the catalytic site, there must be an allosteric site specific for the controlling metabolite.

On the basis of these facts, J. Monod proposed a generalization according to which induction and repression of enzyme synthesis as well as feed-back inhibition of enzyme activity operate by allosteric action. A regulated enzyme has two sites: the enzymatic site and the allosteric site. Fixation of the regulating metabolite on the allosteric site slightly changes the shape of the protein and thus abolishes the activity of the enzyme. In the case of repression and induction of protein synthesis, the repressor produced under the control of the regulator gene is now assumed to be a protein (the evidence in favour of its not being a protein was not very good, and in the case of a lysogenic system there is now evidence that the repressor is probably a protein). The repressor-protein is believed to possess two sites: one of them recognizes the operator and interacts with it, thus locking the operon; the other site can bind the inducer metabolite. When the inducer metabolite is bound, the repressor protein is slightly changed, it loses affinity for the operator and the operon unlocks; a repressor metabolite, on the contrary, increases the affinity of the repressor protein for the operator. This new hypothesis affords a simple model of action of the inducing or repressing metabolite and thus removes one of the greatest difficulties of the previous models of enzyme induction. It also introduces more unity since the regulator gene is now regarded as a structural gene which specifies the repressor protein. The last day of the colloquium was devoted to a completely different field, namely, information in neurophysiology. A. Fessard gave a fascinating course on the mechanisms of brain, the nature of the messages, how they are processed and stored. He first outlined the several levels of organization: wiring diagram of neurones, neurone populations, cellular organization, synapses, membranes, macromolecular structures. He described the activity of the nerve fibre as revealed by the action potentials, and discussed how modulation of the time sequence of successive signals carry information. Depolarization, hyperpolarization and other processes occurring in the dendrite, and the role of the trigger zone in transmitting the messages were described. Then came the spatial aspect of impulse reception in the brain, the interconnexions between neurones, the filtration of signals and the increase of contrast. Great emphasis was laid on the fact that the signals arriving to the brain are not restricted to a small primary area, that they go to many other parts where signals from other types of excitations also arrive. The code in which a certain excitation is translated is assumed to be in terms of patterns.

Finally, the problem of memory was outlined. Fessard described striking experiments on short-term and long-term memory, insisted on the absence of localization of the stored information, and indicated present interpretations. When hearing this lecture after those on enzyme structure and regulation one was led inescapably to think of memory as a regulation process, and to imagine a model in terms of allosteric effects on some synaptic structure. The conclusion of Fessard's lecture was that many of the elaborate properties of the nervous system can be explained by random connexion between neurones, regulated by external actions. A similar conclusion applies to the evolution of the highly organized structure of proteins and nucleic acids. The high information content of the genes, the 'antihasard' which is so obvious in the structure of a protein like hæmoglobin or a double-headed enzyme can have their origin in known random events corrected by the purely deterministic challenge of the external medium. Teleological features of living matter are thus already accounted for in terms of causality.

The participants in this symposium are grateful to their French colleagues, especially Prof. E. Aubel, secretary of the organizing committee, and to the Délégation générale à la Recherche scientifique et technique which provided financial support. The Abbey of Royaumont, the gardens, the musical evenings, and supper by candlelight are delightful memories for those who were privileged to take part in this most successful colloquium.

H. CHANTRENNE

THE INTERNATIONAL ATOMIC ENERGY AGENCY

AN outline of the programme for 1963 of the International Atomic Energy Agency is given in the October issue of the Agency's *Bulletin* (4, No. 4, 11; 1962). A total budget of 9,562,100 dollars has been proposed, representing an increase of approximately 7·5 per cent on the budget for 1962. Estimated expenditure under the heading of the "Regular Budget", financed out of assessed contributions by member states of the Agency, amounts to 7,337,500 dollars. The remainder of the total budget is assessed under the heading of the "Operational Budget" and is financed out of voluntary contributions by member States and other resources, such as funds made available under the United Nations Expanded Programme of Technical Assistance.

The Agency's technical assistance programme is to be extended. During 1962 requests for assistance involving the services of 40 experts, and equipment worth nearly 230,000 dollars were approved. This was in addition to some 36 experts already serving during 1962 under previously sanctioned projects. During 1963 the need will arise for the services of some 90 field experts, in addition to those whose assignments continue from previous years. Requests for equipment are expected to exceed the value of 250,000 dollars.

The Agency's training programme includes the award of fellowships and research grants. The number of applications for fellowships has increased steadily, but there has not been a corresponding increase in the funds available for the purpose. Hence during 1963 more extensive use is to be made of cost-free fellowships made available by member States, but even then it is anticipated that not all deserving requests will be able to be met. For use in training on the spot the Agency provides two mobile laboratories. Approximately 750 trainees in the Far East, Latin America and Europe have used these laboratories in the past years, and it is expected that one of the laboratories will move to Africa late in 1962 or early in 1963.

A number of conferences and symposia are planned for 1963. A panel of experts is to meet to discuss the Agency's report on the results of an investigation into the cost of nuclear power in an integrated system and its comparison with the cost of conventional power production, and another group of experts will discuss the physics of heavy-water lattices. Symposia are to be held on materials for reactor control, including their metallurgical and physical properties and their design and fabrication; on new nuclear materials technology, with special reference to the use of such materials in the fabrication of non-metallic fuel elements; on the use of radioisotopes and radiation sources for the control of plant pests; on the use of isotopes in hydrology; on the biological effects of neutron irradiation and on the effects of radiation on the endocrine system; and on radiological health and safety in the mining and milling of nuclear materials; and the Agency's Scientific Advisory Committee has recommended that a seminar be held on some aspect of nuclear, solid-state or plasma physics.

Research contracts in tropical medicine are to be awarded with the view of promoting the application of established radioisotope techniques to the study of diseases affecting large groups of people in the less-developed countries in tropical regions. A review is to be made of the results of the Agency sponsored research on calcium-47, and work on the calibration and standardization of measurements of uptake of radioiodine by the thyroid gland is to continue. The distribution of calibrated radionuclide samples will be extended during 1963 and new calibration methods will be developed. Participation in the international intercomparison measurements of radionuclides organized by the International Bureau of Weights and Measures will continue. The comparative study of methods used in different laboratories for the chemical analysis of nuclear materials; the determination of trace elements in the marine environment; and in mass spectroscopy, the programme of the application of stable isotopes to analyses by the isotope dilution method, and the direct analysis by the mass spectrograph of trace elements in sea-water and nuclear materials, are some of the investigations to continue or be commenced during the year.

There are indications that during 1963 a number of nuclear facilities will be subject to Agency safeguards, and plans are being made to buy the essential minimum of portable equipment needed for the inspections. The general problems of emergency conditions in the event of a serious accident in nuclear installations are to be reviewed and the Agency's plans for the provision of international emergency assistance to member states are to be extended. Increased attention is to be directed to the development of techniques to deal with the disposal and management of radioactive waste, atmospheric pollution, and the transport and distribution of radioactive material. In this connexion, any necessary revision to the Agency's regulations for the safe transport of radioactive materials will be considered.

S. WEINTROUB

FOREST RESEARCH

THE report on forest research for the year ended March 1961* shows the wide range of work being carried out by the Forestry Commission Research Staff and for the Forestry Commission, with assistance by workers at universities and other institutions.

Much more attention is now being paid to the forest soil. Drainage is often a great problem. Wet soils may have a severe effect on tree roots by inhibiting growth and also by making the trees vulnerable to windblow. With the machines now available, the initial drainage system for a bare area may not be a very difficult task but a great deal more information is required on the depth drains should be on a given site and how far apart they should be spaced in order to provide reasonable conditions for afforestation purposes. The subsequent problems include the maintenance of the drains and, unfortunately, there is quite a lot of evidence in Britain of neglected drains. However, ways and means for ensuring the provision of good drainage in forest areas are being investigated. Nutritional work is also being undertaken. The analysis of foliar samples from fertilizer trials is providing data on nutrient deficiencies. Another series of experiments is attempting to elucidate the role of mites in the breakdown of forest litter.

For the first time a report on work study is included. The activities of the section dealing with this cover investigations on tools, equipment, machinery, piecework and other matters affecting production operations at all levels.

A prototype direct-reading calliper has been developed and trials of this instrument have demonstrated that enumeration work can be speeded up and so costs are reduced. As the measurements are transferred directly on to a tape by a punch system, errors in recording can be avoided. Two plates show some details of this calliper but no details are given of its weight. At least two other types of self-recording callipers are in use in Scandinavia.

In the report of the New Zealand Forest Service's Forest Research Institute for 1961†, mention is made of the new requirement that although officers out with the Research Division are still encouraged to conduct their own research projects, these must be approved by the Director of Research. This is a wise ruling. The individual is not thwarted, co-ordination is possible and one of the great drawbacks to individual research in forestry will be avoided, namely, the discontinuance of an experiment through the transfer of an officer to another territorial charge.

It is good to read that one of the planned developments is in physiology and the reason given is "because it is basic to an understanding of many problems in the fields of silviculture, forest-tree improvement and forest pathology". Another development is the appointment of a "silvicultural economics" team with the object of constructing financial yield tables for exotic species. This shows a realistic approach to land-use evaluation and will form a proper basis for the assessment of the relative merits of agriculture and forestry whenever such is required and it is expected to be more needed in the future. In addition, it is felt in New Zealand that a new approach is required in forest economics which, for so long, has been conditioned by European practice.

There is nothing perfunctory about the forest research described in this report. Indeed, the reader is convinced that forest research in New Zealand is well planned and vigorous, and that, in addition to trying to solve present-day problems, it is also forward-looking in a very commendable way.

ASPERGILLUS FLAVUS AND GROUNDNUT TOXICITY

IN 1960, large numbers of young turkeys in Britain died (and, later, other domestic birds and farm animals were shown to be affected) for a reason that was at first unknown and was called 'turkey X disease'. This was later shown to be due to the presence of a toxic batch of groundnut meal in their 'feed'. As a result of this, a number of Government and other research laboratories studied this toxicity as a matter of urgency. Real progress became possible with the demonstration that the toxin was not intrinsic to the groundnuts themselves but was the product of a mould (a strain of *Aspergillus flavus*) growing on them. This toxin-producing mould is widespread, and it was not surprising, therefore, that the toxin was identifiable on some samples of groundnuts or meal from all the main producing areas.

Because the problems posed overlapped the responsibilities of a number of Government departments, an

Interdepartmental Working Party was set up to review and co-ordinate research relevant to groundnut toxicity. In August 1962 the report * of this Working Party was circulated to overseas Governments and to the Press, and was made available to those in Britain and overseas known to be concerned in the production and utilization of groundnuts.

The report provides an account in general terms of the nature of the problem and means of identifying affected batches of nuts or meal. Suggestions are made as to how mould growth can be minimized and toxin-levels be kept down.

The report should prove of value to those who produce, market, process or use groundnuts, and should also stimulate necessary further research on groundnut toxicity, especially in the producing areas themselves.

POLARIZATION AND CLASSIFICATION OF RADIO SOURCES

By Dr. R. D. DAVIES and G. L. VERSCHUUR

Nuffield Radio Astronomy Laboratories, University of Manchester, Jodrell Bank, Macclesfield

THE detection of polarized radio emission from the radio sources Cygnus *A* (ref. 1) and Centaurus *A* (refs. 2 and 3), and a group of weaker sources[4], opened a new phase on the investigation of these objects. As well as the angular structure and spectrum, the percentage and position angle of polarization of radio sources are now available. This article gives the results of an examination of ten further radio sources of small angular diameter and relates the present polarization data and that obtained by Gardner and Whiteoak[4] to other known properties of radio sources.

The receiver used was basically that utilized for the Zeeman experiment[5], but was modified to measure the difference of intensity between two orthogonal planes of linear polarization. The frequency was 1,410 Mc/s and the band-width 5 Mc/s. Using a 20-sec time-constant, it was possible to detect differences in polarization of 2×10^{-27} Wm^{-2} (c/s)$^{-1}$ in the weaker radio sources studied. Measurements were taken by allowing the beam of the 250-ft. radio telescope to drift across the source at one position angle of the horn feed system and then repeating at a position angle 45° different. Sources were observed at several different hour angles. The system gave a spurious response of several per cent of the source flux which was constant and was allowed for. The measurements were made in the first week of October 1962.

This programme was confined to a group of 3*C* sources which had a galactic latitude (b'') greater than 12° and included representatives of the classes of radio objects identified with stars, double sources and sources with a core and halo. They also showed a wide range of spectral types, brightness temperature and redshift. The new polarization data obtained at Jodrell Bank are shown in Table 1.

The optical results quoted in Table 1 are those given by Maltby, Matthews and Moffet[6] and by Burbidge[7], and the radio information about the structure of the sources comes from published measurements at 160 Mc/s (refs. 8 and 9), 960 Mc/s (ref. 10) and 1,420 Mc/s (ref. 11). The results agree with the Sydney data for the sources common to both lists, namely, 3*C*348 and 3*C*353. In addition, it was found that Cassiopeia *A* was less than 0·3 per cent polarized and Taurus *A* was 1·0 ± 0·2 per cent polarized at position angle 82° ± 8°.

This data can be combined with that obtained in Sydney, also taken at 1,400 Mc/s. However, in order to make the measurements on the extended objects Centaurus *A* and Fornax *A* uniform with the present measurements the integrated polarization of the entire object was calculated. In Centaurus *A* the central double core is 7 per cent polarized and the large double halo was estimated to be 11·5 per cent polarized at most. The integrated emission from Fornax *A* was 7·4 per cent polarized. The combined data included 11 sources which are double systems at radio frequencies, 3 which consist of a bright central core and an extended halo of lower luminosity and 3 which have been tentatively identified with stars[7].

Cygnus *A* will be included in the following discussion although it lies only 6° above the plane and its polarization is effected by Faraday rotation in the Galaxy which amounts to about 10 rotations at 1,400 Mc/s, corresponding to an emission measure of ~ 200 in the outlying areas of Cygnus *X* which envelop Cygnus *A*. A variation of 10 per cent in the Faraday rotation across the source will be sufficient to cause complete depolarization at this frequency. At 3-cm wave-length the total rotation would amount to ~ 100° and the depolarization would be expected to be negligible. Thus the observed[1] polarization of 8 per cent found at 3 cm will be adopted as the polarization of the signal leaving Cygnus *A*. This step is justified by the observations of Centaurus *A* at $b'' = +20°$, which show the same polarization of the bright central component from 1,400 Mc/s to 10,000 Mc/s and also by the manner Cygnus *A* fits into the picture of double radio sources in the following discussion.

The observed position angle of the received signal from the sources in Table 1 show no correlation with the axes of symmetry of the associated optical objects. This is in agreement with the Sydney[4] and N.R.L.[1] findings and is the result of different amounts of Faraday rotation between the source and the receiver for different sources.

Table 1. PERCENTAGE POLARIZATION AND POSITION ANGLE OF THE ELECTRIC VECTOR FOR TEN SOURCES MEASURED AT 1,410 Mc/s AT JODRELL BANK

Source	Polarization (per cent)	Position angle	Identification	Distance (Mpc)	Comments
3*C*48	1 ± 1	70° ± 10°	Star	—	Diameter less than 1″ at 160 Mc/s.
3*C*84 Perseus *A*	5 ± 1	36° ± 10°	*NGC* 1275 Two spiral galaxies	53	Appears to be a core and halo at radio frequencies.
3*C*123	4·5 ± 1·5	8° ± 10°	—	—	Two components 12·5″ apart E.W. Component size 5·3″.
3*C*196	10 0 ± 0·5	49° ± 2°	Star	—	Diameter ~ 5″.
3*C*274 Virgo *A*	< 0·3	—	*NGC* 4486	12	Core and halo at radiofrequencies associated with elliptical galaxy and jet.
3*C*286	12 ± 1·5	31° ± 2°	Star	—	Diameter ~ 1″.
3*C*295	6·0 ± 1·0	162° ± 4°	20·9 m galaxy	1,380	Two components 4″ apart. Component size ~ 1·7″.
3*C*348 Hercules *A*	2 ± 0·5	6° ± 5°	19 m galaxy	460	Two components 1·95″ apart. Component size ~ 0·75″.
3*C*353	6 ± 0·5	7° ± 10°	16·8 m galaxy	(250)	Two unequal components. 2·5′ apart. Component size ~ 1·4′.
3*C*405 Cygnus *A*	< 0·3	—	15·3 m galaxy	170	Two components 1·58′ apart. Component size ~ 0·7′.

Polarization and spectral characteristics. The relationship between the percentage polarization P and the detailed spectral information given by Conway, Kellerman and Long[12] was investigated. No close correlation between polarization and the mean spectral index in the range 38–3,200 Mc/s was found although there is a tendency for the spectral index (α) to increase from 0·5 for the strongly polarized sources to 0·9 for the weakly polarized sources. However, a much stronger correlation (Fig. 1) exists between the polarization amplitude and ρ, the ratio of expected flux at 3,200 Mc/s extrapolated from the low frequencies to the observed flux at 3,200 Mc/s; ρ is a measure of the curvature of the spectrum at the high frequencies. The 7 double sources show a close correlation between P and ρ; the limits of the range are represented by 3C273 for which $P < 1$ per cent and $\rho = 0·95$, and by 3C270 for which $P = 8$ per cent and $\rho = 1·82$. The stars and single sources with halos show a scatter on Fig. 1.

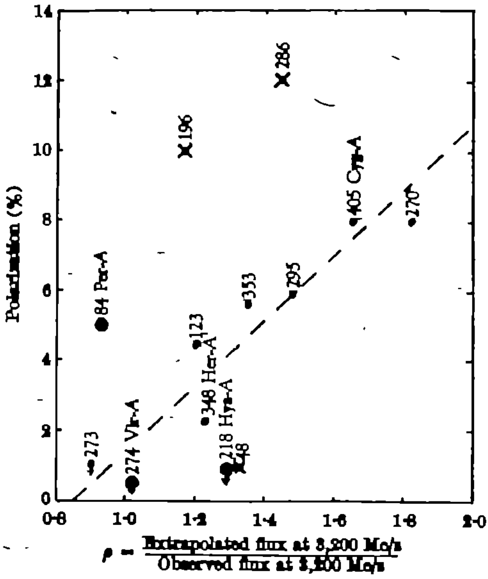

Fig. 1. Percentage polarization (P) plotted against ρ the ratio of the flux at 3,200 Mc/s extrapolated from low frequency measurements to that actually observed at 3,200 Mc/s

Stars are shown as ×, sources with a halo and bright core as ⊙, and double sources as ●

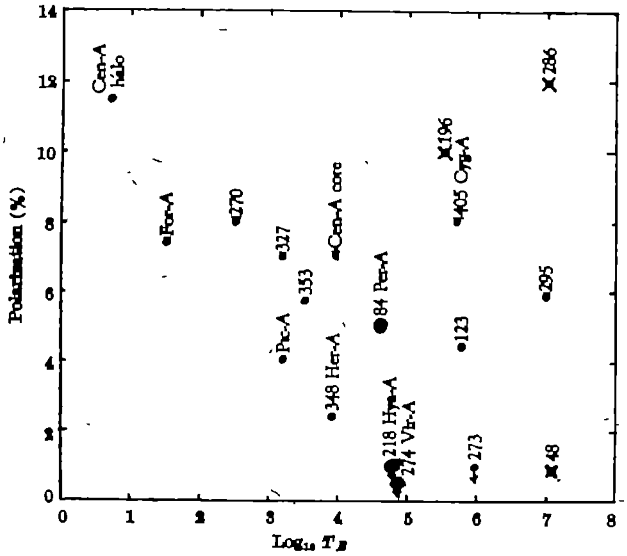

Fig. 2. Percentage polarization (P) plotted against the brightness temperature of the source. In the case of sources with a core and halo the brightness temperature of the core is taken. For Centaurus *A* the double core and the double extensions (halo) are plotted separately. The symbols are as for Fig. 1

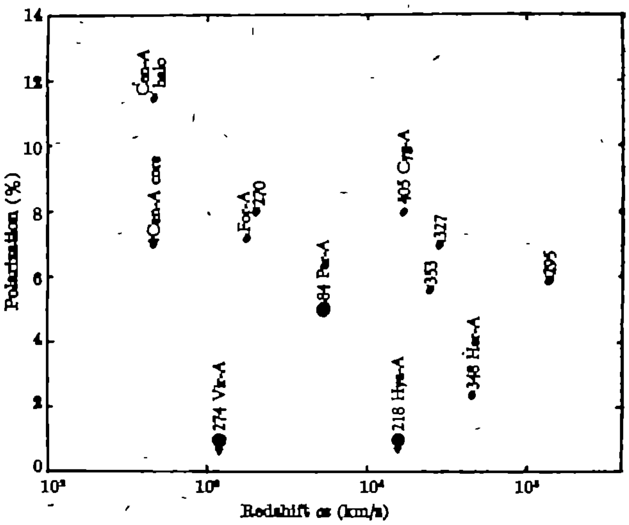

Fig. 3. Percentage polarization P plotted against redshift cz in km/s. The symbols are as for Fig. 1

Polarization and brightness temperature. A plot of P against T_B, the brightness temperature, of the sources studied is shown in Fig. 2. The correlation between P and T_B is small. If the sources identified with stars are excluded there is a weak tendency for the polarization to fall with increasing brightness temperature. However, the scatter is so great that this tendency is unlikely to be significant.

Polarization and redshift. The redshift of extragalactic objects in the combined list of sources which have been investigated for polarization are shown in Fig. 3, as a function of polarization. Again, there is no correlation with redshift even out to the distance of 3C295 for which $d\lambda/\lambda = 0·46$ (ref. 13). This result is significant as it indicates that there is no depolarization in the intergalactic medium. Complete depolarization would occur during an increase of a factor of two in distance where differential rotation increases from 45° to 90°, say, and this would appear as a rapid fall in P with redshift in Fig. 3.

Properties of different classes of object. The radio properties of the 17 observed sources in three classes are summarized in Table 2. It is tentatively suggested from these results that the three types of object may be distinguished by their radio properties alone. Two of the three so-called stars have a polarization of 10 per cent or more and it seems that this class of object is characterized by high polarization and high brightness temperature. The three objects consisting of a bright core and a halo show low polarization, nearly straight spectra ($\rho \simeq 1·0$) and intermediate brightness temperatures. The one object in this class which shows any significant polarization is Perseus *A* (3C84); it may possibly be part of a double system consisting of 3C84 and 3C83.1; measurements were not made on 3C83.1, so it is not at present possible to tell whether this double system fits the other data for doubles presented here or whether it is a halo object like Virgo *A* (3C274). The double sources show a strong correlation between the polarization P and ρ which is a measure of the curvature of the high-frequency part of the spectrum.

The classification of radio objects using the properties outlined above may be important in assessing the nature

Table 2. RADIO PROPERTIES, 'STARS', HALO SOURCES AND DOUBLE SOURCES

	1,400 Mc/s polarization (%)	Spectral characteristics α	ρ	Brightness temperature (T_B (°K))	Structure
Stars	~ 10	~ 0·5	~ 1·8	> 10⁶	Single
Halo sources	$\lesssim 2$	~ 0·8	~ 1 0	~ 5 × 10⁴	Core and halo
Double sources	0–8 (correlation with ρ)	0·4–1·0	1·0–1·8	10¹–10³	Double

of the unresolved radio objects at large distances and those for which optical identifications cannot easily be made or are in question. Further observations are needed to verify this classification.

Double radio sources. The close correlation between P and ρ for the double sources is of particular interest as it throws light on the nature of these objects. One picture of these objects which will give rise to this correlation will be presented. It is proposed that these are expanding objects of various ages in which synchrotron radiation is emitted by relativistic electrons generated in the system which spiral around the lines of a magnetic field also generated in the system. Thus at an early stage the proportion of high-energy electrons will be greater and the spectrum will be enhanced at medium and high frequencies. However, these high-energy electrons radiate more quickly than low-energy electrons and there will be a sharp drop in the spectrum at the high frequencies. As the object ages the contribution from the high-energy electrons disappears and the spectrum reduces to a constant slope over most of the frequency-range. In the early stages the proportional rate of increase of volume is greatest and the field lines are being rapidly expanded to give a more uniform field through the object than at a later epoch when the rate of expansion is slower. The percentage polarization observed in synchrotron emission increases with the uniformity of the field and will thus be greatest for a young object. Accordingly, both P and ρ will be indicators of the age of double systems on this model. The duplicity of the systems may be the result of enhanced radiation at the two mirror points in the enclosed magnetic field of the expanding object.

If this picture is correct the spectrum of the young objects will be flatter than that of older objects and accordingly there should be a negative correlation between P and α, the mean slope of the spectra. Such a tendency has already been noted in a previous paragraph.

At first sight it might be expected that the brightness temperature should be high in young sources with a high energy relativistic electron component. However, it must be remembered that T_B is also a function of the number density of relativistic electrons and of the magnetic field and variations from source to source in the latter quantities may remove any correlation between P and T_B. Indeed, this lack of correlation is evident in Fig. 2, and it was also found that for the sources studied there was no close correlation between T_B and ρ.

Cosmological implications. Since $3C295$ shows the expected amount of polarization for its value of ρ then the amount of depolarization it has undergone in the Milky Way halo, in the intracluster medium of our own system of galaxies, in the intracluster medium of the system of galaxies to which $3C295$ belongs and in the intergalactic medium must be less than ~ 30 per cent. This would be caused by differential rotation between the two components of the source of less than 30° or 0·08 rotation. Such a difference of rotation would occur between two paths which leave $3C295$ 27 kpc apart, the separation of the components of $3C295$, then pass through our local cluster at a mean distance of 0·5 Mpc at 10 pc apart and enter the halo of the Milky Way 0·2 pc apart.

In the case of the interglactic medium the differential rotation will occur owing to variations of magnetic field or electron density or both between the two paths. If the intergalactic medium has sub-units 2 Mpc in diameter 30 Mpc apart which eventually form clusters of galaxies with density variations of 10 : 1 about the mean over this distance then the density variation is 10 per cent of the mean density for 10 kpc, the mean separation of the two paths. A variation in the direction and magnitude of the intergalactic magnetic field alone would give a Faraday rotation variation of the same order for each sub-unit. If there are about 20 sub-units ~ 50 Mpc apart lying between our Galaxy and $3C295$ this would lead to an increase of about 5 and a total differential Faraday rotation of ~ 100 per cent on the paths to the two components of $3C295$. Even if only 3 : 1 variations in density and field were assumed the differential rotation would still be 30 per cent of the whole and thus the total rotation to avoid depolarization would need to be much less than 0·25 rotations. At 1,410 Mc/s the number of rotations $= 6 \times 10^3\ Ne\ H\ L$ where Ne is the number of electrons per cm^3, H is the field in gauss and the path length L is in parsecs. Thus the mean value of $Ne\ H$ is $< 3 \times 10^{-14}$ for the intergalactic medium between the Milky Way and $3C295$.

A similar calculation for the intracluster case assuming density and field variations of 3 : 1 over 300 kpc (the distance apart of galaxies) in a cluster with a diameter of 2 Mpc shows that the mean rotation need only be 0·08 rotation. The corresponding value of $Ne\ H$ for the $3C295$ cluster is $< 1{\cdot}3 \times 10^{-11}$.

Both these results appear to be in conflict with the hot version of the steady-state universe proposed by Gold and Hoyle[14] in which the intergalactic and intracluster gas is ionized hydrogen having densities of 2×10^{-5} and 10^{-3} cm^{-3} respectively. With an intergalactic magnetic field of 10^{-7} gauss[14] the density is $< 3 \times 10^{-7}$, which is more than an order of magnitude less than that proposed. With an intracluster field of 3×10^{-7} gauss the corresponding density is $< 4 \times 10^{-5}$, again an order of magnitude less than the predicted value. In a more recent discussion[15] the intergalactic magnetic field strength is suggested to be 10^{-6} gauss, which would result in an upper limit of the intergalactic density 600 times less than required in the steady-state theory and an intracluster density more than a factor of 100 times less than required.

This result for the cluster medium also has a bearing on the discussion[2,15,16] of the origin of the Faraday rotation between Centaurus A and the Earth. If the density derived here for the cluster with which $3C295$ is associated is typical of the local cluster then for a field of 10^{-6} gauss $Ne\ H\ L < 10^{-5}$ for a depth of 1 Mpc, whereas the value required is $\sim 10^{-4}$. Thus the cluster medium cannot give the rotation required and it is likely that the nearer parts of the Milky Way provide the rotation as argued by Cooper and Price[16]. A region which can provide the required rotation is the galactic spur if it is considered as a typical old supernova remnant[17]. It extends into the vicinity of Centaurus A. The expanding shell will have a hydromagnetic shock region which compresses both the magnetic field and the gas which will be ionized. A model of the spur object[18] gives densities in the brighter regions of ~ 10 cm^{-1} and a magnetic field of $\sim 10^{-5}$ and a shell thickness of ~ 5 pc when observed at the edge. The corresponding value of $Ne\ H\ L$ is 5×10^{-4}, which is sufficient to give the rotation.

SIMULTANEOUS RADAR AND REFRACTOMETER SOUNDINGS OF THE TROPOSPHERE

By J. A. LANE and R. W. MEADOWS

Radio Research Station, Department of Scientific and Industrial Research, Ditton Park, Slough

IN research on tropospheric wave propagation, the explanation of the transmission of very-high-frequency signals to points well beyond the horizon has been a subject of considerable interest for many years. Several workers[1,2] have suggested that, in the absence of super-refraction, the propagation mechanism is one of 'forward scatter' from random irregularities in refractive index which are always present, to some extent, throughout the troposphere. However, the validity of these theories, which are based on the statistical analysis of atmospheric turbulence, is still uncertain. Recently, other models of the troposphere have been proposed which, while retaining the concept of scattering as the operative mechanism in certain conditions, emphasize the importance of extended 'layer-type' irregularities[3]. These features are thought to exist in their most pronounced form in the stable air of temperature inversions.

Experimental investigations of refractive index irregularities in the troposphere are of fundamental importance in clarifying these problems, and it is the purpose of this article to summarize some recent work in this field at this Radio Research Station. The objective in the experiments was to compare the data provided by soundings of the troposphere by radar, as suggested in the early work of Friend[4], and by airborne microwave refractometers. The latter instruments were flown in aircraft of the Meteorological Research Flight, Farnborough, and spiral ascents and descents near the vertical beam of a radar transmitter were made whenever possible during the period July–November 1961 over a site at Bramshill Park in Hampshire. Special efforts were made to carry out joint soundings in clear weather conditions to avoid any confusion due to echoes from cloud and precipitation.

The airborne refractometers used for measuring the atmospheric refractive index were of the type developed by Birnbaum[5], and some details of their construction and of the procedure followed in airborne measurements have been given elsewhere[6]. With this type of refractometer the air passes continuously through a substantially open-ended microwave cavity resonating (in this case) near 10 Gc/s. The exact resonant frequency is inversely proportional to the instantaneous value of refractive index to be determined, and is measured automatically by a sweep-frequency technique. The refractive index fluctuations so determined were recorded on photographic paper, and height markers were inserted manually on the record as required. The soundings were afterwards re-plotted in profile form showing refractive index as a function of height. The rate of ascent or descent was generally 5 m/sec.

The vertically pointing radar equipment used in the tests operated with a single paraboloid aerial 8 m in diameter having a gain of 34 db at 3 Gc/s. The peak power of the transmitter was 500 kW and the pulses were 0·1 μsec wide repeated 500 times per sec. With a receiver band-width of 30 Mc/s and a noise-factor of 8 db a signal of strength 121 db below 1 W produced a root mean square signal/noise ratio of unity. The echoes were displayed on a vertical time-base by brilliance-modulation adjusted to produce limiting brightness at a signal-level just above that of the majority of the thermal noise peaks. This vertical line was moved horizontally at a steady slow

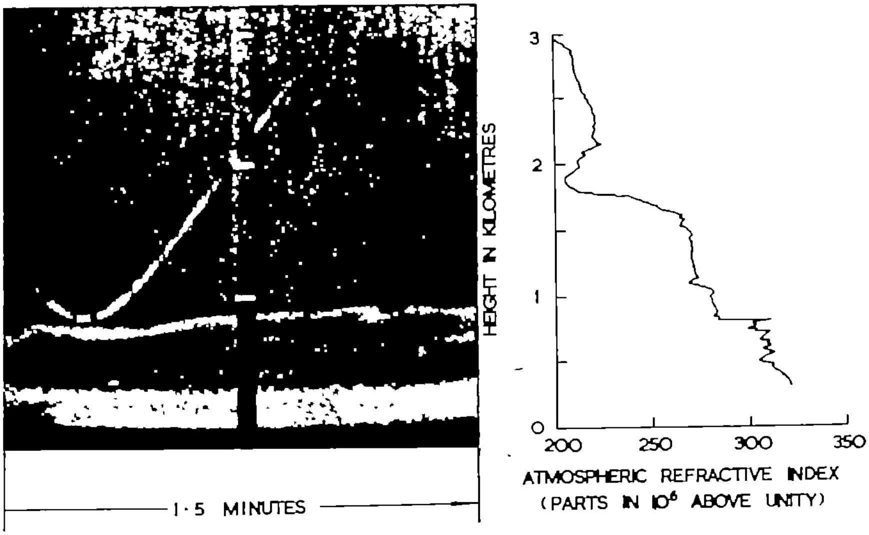

Fig. 1. Simultaneous radar and refractometer soundings at 15 10 h G.M.T. on August 29, 1961

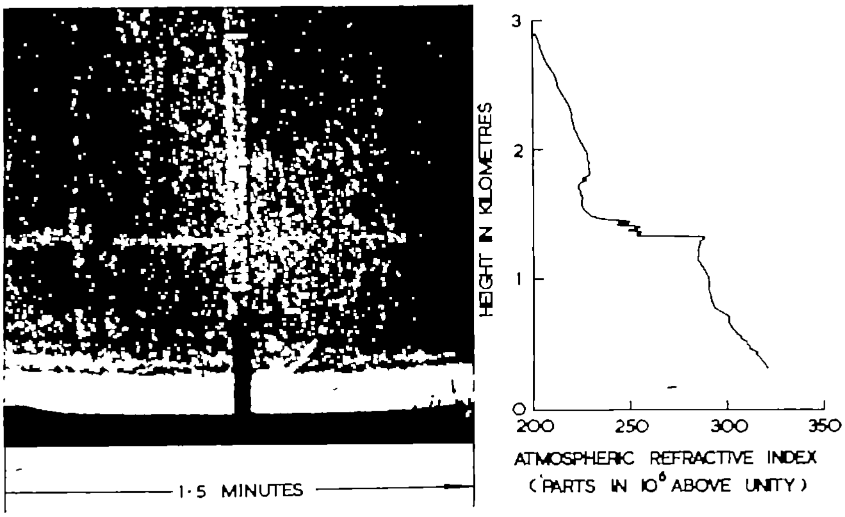

Fig. 2. Simultaneous radar and refractometer soundings at 17.55 h G.M.T. on August 29, 1961

rate to cover a photographic plate in about 1·5 min, and produced the pictures illustrated in Figs. 1 and 2, where height-markers 1 km apart are also shown. A useful amount of 'integration' was introduced by the photographic process, and enabled signals to be detected at a level of 134 db below 1 W corresponding to an amplitude reflexion coefficient of about 3×10^{-8} at a layer at a height of 1 km.

The results of the experiments may be summarized as follows. The characteristic, layer-type echo sometimes observed by radar[7] was generally found to correlate with a sharp gradient in the refractive index profile, at the corresponding height. On the other hand, the refractometer sometimes recorded a marked irregularity which was not observed by radar. These different characteristics reflected not only the effect of the overall sensitivity of the equipment, but also the degree of coherence in the scattered radiation together with the detailed structure and orientation of the layers. When the refractometer sounding showed a well-mixed atmosphere with no pronounced irregularities in the profile, no layer-type radar echoes were detected. Figs. 1 and 2 illustrate some of the results obtained in joint soundings made during anticyclonic conditions, at 15.10 h and 17.55 h G.M.T. on August 29, 1961. In Fig. 1, both techniques reveal a major irregularity in the refractive index profile at a height of about 0·8 km, the radar echo indicating the presence of an extended, slightly undulating layer. Ground-clutter extending to a range of about 0·3 km is also visible in Fig. 1, together with a curved trace showing the variation of aircraft range as it flew through the aerial side-lobes. At 15.10 h, no definite echo could be detected from the refractive index irregularity at 1·8 km, the height of the main subsidence inversion. By 17.55 h, however, the lower layer had disappeared from both records and the joint soundings in Fig. 2 show a single major irregularity at a height of 1·4 km. Detailed inspection of the original refractometer data shows that in the lowest portion of the irregularity illustrated in Fig. 2 the refractive index apparently changes by 30 parts in 10^6, in a vertical interval of a few metres. These soundings, and others made on the same afternoon, indicate that the main irregularity or layer shown in Fig. 2 was descending at a rate of about 100 m/h.

The results confirm the presence of extended layers in the refractive index structure of the troposphere and emphasize the value of combined radar and refractometer soundings in the investigation of the distribution of refractive-index irregularities and their scattering properties. A full account of this work is in the course of preparation.

This work has involved the participation of many of our colleagues and members of other organizations, in particular, the Meteorological Office and the Royal Aircraft Establishment. It is part of the programme of the Radio Research Board, and is published by permission of the Director of Radio Research of the Department of Scientific and Industrial Research.

HELIUM ION BELT IN THE UPPER ATMOSPHERE

By DR. S. J. BAUER

Space Sciences Division, National Aeronautics and Space Administration,
Goddard Space Flight Center, Greenbelt, Maryland

EXPERIMENTAL evidence for the presence of helium ions in the upper atmosphere in accordance with Nicolet's[1] suggestion is now available from ion- and electron-density profiles[2,3], ion probe retarding potential experiments[4,5], and direct measurements with radiofrequency ion spectrometer[6]. Hanson[2], who first inferred the presence of He+ from an experimental ion-density profile obtained by Hale[7], concluded that the thickness of the belt of helium ions is of the order of 2,000 km, extending from 1,200 km to about 3,400 km.

Because of the presence of He+, the upper ionosphere has to be considered a ternary ion mixture (O+, He+ and H+). Although the diffusive equilibrium distribution of a minor ion species in an ion mixture is influenced by the others (unlike neutral constituents) because of the electric field resulting from the slight charge separation between electrons and positive ions[8,9], the relative concentrations of ionic species behave like neutral constituents. The boundaries of a region where an ionic species predominates can be defined by the transition or equal-concentration levels, that is, the levels where the concentration of this species is equal to that of the neighbouring ionic species.

The equal-concentration level (h_{ij}) can be expressed in terms of the geopotential height parameter[10]:

$$z'_{ij} = H_{ij} \ln \eta_{ij} \qquad (1)$$

where $z'_{ij} = h'_{ij} - h'_0$ is the geopotential distance between the equal-concentration level and the reference-level h'_0 at which $[X_i^+]/[X_j^+] = \eta_{ij}$, and $H_{ij} = kT/(m_i - m_j)\, g_0$ with k the Boltzmann constant, T the absolute temperature, m_i and m_j the masses of the ionic species X_i^+ and X_j^+ and g_0 the acceleration of gravity at the Earth's surface. The geopotential altitude h' is related to the geometric altitude h by $h' = \int_0^h (g(h)/g_0)\mathrm{d}h$. In this discussion the subscripts 1, 2 and 3 refer to O+, He+ and H+, respectively.

The actual situation is complicated by the fact that the relative ion concentrations at the reference-level (η_{ij}) are also a function of temperature. This is particularly true for the ratio η_{31} since the neutral hydrogen concentration at a constant altitude depends on the rate at which it escapes from the upper atmosphere. Since this escape rate increases with temperature, the concentration of hydrogen at a constant level increases with decreasing temperature. The ratio [H]/[O] at an altitude of 500 km, which we shall adopt as reference-level h_0, increases by a factor of 100 for a temperature decrease from 2,000° K to 1,000° K[11,12]. If the proton concentration is governed by the charge exchange equilibrium condition[11] the ratio η_{31} varies with temperature in the same proportion as the ratio of the neutral constituents. The same argument applies if photo-ionization rather than charge exchange is responsible for the protons. Similarly, a proportional variation of [He]/[O] and η_{21} with temperature can be assumed. The helium concentration at 500 km varies only slightly with temperature[12] so that the ratio η_{21} will not vary as strongly with temperature as η_{31}.

The following values have been adopted for the present model: The concentration ratio [H+]/[O+] at 500 km varies from $\eta_{31} = 10^{-4}$ at 1,600° K to $\eta_{31} = 10^{-8}$ at 600° K, while the ratio [He+]/[O+] at 500 km varies from $\eta_{21} = 5 \times 10^{-2}$ at 1,600° K to $\eta_{21} = 5 \times 10^{-3}$ at 600° K. The temperature-range corresponds to the extremes for the present level of solar activity. The chosen variation with temperature of η_{31} is in good agreement with Bates and Patterson[11], and that for η_{21} is consistent with the variation of the helium concentration of Nicolet and Kockarts[12].

Fig. 1 shows the transition-levels h_{12} ([He+] = [O+]) and h_{23} ([H+] = [He+]) as a function of atmospheric temperature for the assumed variation of η_{ij} at the reference level h_0 = 500 km. The altitude difference $(h_{23} - h_{12})$ between the two equal-concentration levels may be called the thickness τ of the helium ion belt. It is obvious that this thickness is drastically reduced as the temperature decreases.

If the thickness τ is less than the local scale height for helium ions ($\tau < H(He^+)$), that is, if the two equal-concentration levels h_{12} and h_{23} occur within one scale height, no distinct slope corresponding to He+ will be distinguishable in an ion or electron density profile. This is the case for temperatures of the order of 1,000° K or less. Fig. 2 shows normalized charged particle density profiles based on a ternary ion mixture[10] for 800° K, 1,000° K and 1,300° K and corresponding η_{ij} versus geopotential distance z' above the reference-level, illustrating the fact that identification of helium ions from profiles is virtually impossible for low temperatures. A recent night-time electron density profile[13] failed to show evidence for the presence of He+. In the light of the foregoing discussion, failure to detect He+ from a profile does not prove the absence of He+ but can be explained by the fact that the thickness of the helium ion belt at that time was comparable in magnitude to the scale height of He+.

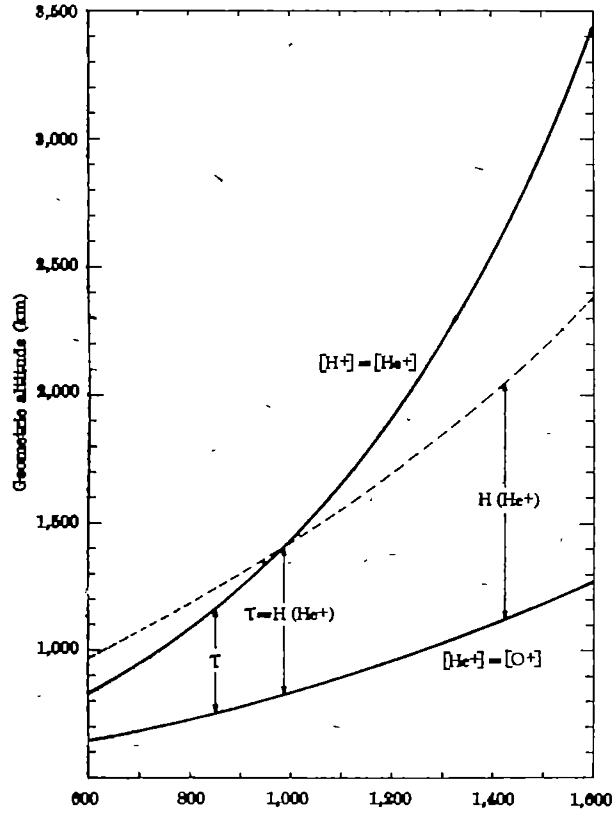

Fig. 1. Equal concentration-levels [He+] = [O+] and [H+] = [He+] on a geometric altitude scale versus atmospheric temperature. τ represents the thickness of the helium ion belt, while the local scale height for He+ is indicated by the distance between the dashed curve and the [He+] = [O+] curve. The equal-concentration-levels are based on the temperature-dependent ion concentration ratios (η_{ij}) at 500 km given in the text

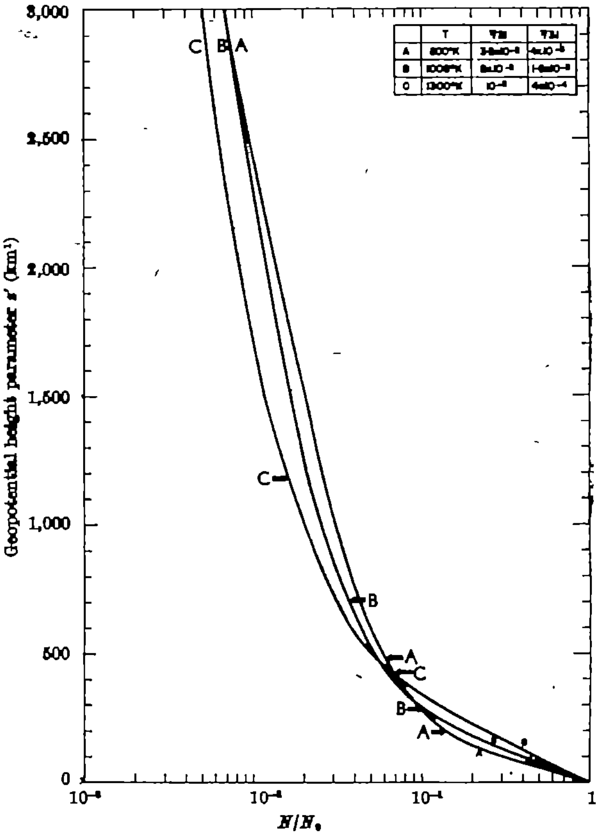

Fig. 2. Normalized charged particle density profiles for a ternary ion-mixture as a function of geopotential distance z' above the reference-level, corresponding to the listed ion concentration ratios (η_{ij}) and atmospheric temperatures. The solid arrows indicate the equal concentration level [He+] = [O+] and the open arrows [H+] = [He+]

In fact, from another recent night-time ion-density profile measured by a National Aeronautics and Space Administration rocket, the presence of helium ions is also not obvious[6]. However, a preliminary retarding potential analysis of the same data indicates the presence of all three ionic constituents (O+, He+ and H+). The combined ion density and composition data are thus consistent with the concept of a thin helium ion belt at low atmospheric temperatures.

Further refinements of the model presented here can be expected as the result of the ion-composition measurements on the *Ariel* satellite[14].

Note added in proof. From the final analysis of a recent ion density profile[6], it appears that the equal-concentration levels at the corresponding temperature of 800° K are about 200 km lower than indicated in Fig. 1, while the thickness of the helium ion belt is in good agreement with the present model. This fact seems to imply an even stronger temperature-dependence of the ion concentration ratios η_{ij} than was assumed here.

METEORITE IMPACTS, LUNAR MARIA, LOPOLITHS AND OCEAN BASINS

On the assumption that one giant meteorite has fallen about every 10,000 years on our planet, R. Dietz estimates that some 50,000 of such missiles may have struck during the past 500 million years, or since the beginning of Cambrian times[1].

It is not very clear what is meant by "giant meteorites". If we refer to the data given by astronomy, the masses of the cosmic bodies indicated by Dietz may roughly be evaluated at 10,000 metric tons each[2]. Following the calculations made by M. Innes[3], such meteorites would produce craters of about 750 metres in diameter at an impacting speed of 20 km/sec.

As the question of the mass of striking bodies is still subject to controversial discussion, it would appear better to define a "giant meteorite" by the dimension of the crater it produces and to admit conventionally that those words refer to a missile able to produce a crater of at least 1 km in diameter at the impacting speed of 20 km/sec. In this case, the Barringer Crater (Arizona) represents the scar of a giant meteorite of about 5×10^4 metric tons, as calculated by Innes[3].

Rudaux and de Vaucouleurs mention that a meteorite of 5×10^4 metric tons—or more—strikes the Earth about every 100,000 years. They emphasize that this estimate is very conservative as most of these impacts must have escaped direct observation[2]. There is thus a good agreement between the evaluations given by geophysicists and those accepted by astronomers.

As there is no doubt that cosmic bodies have fallen at all times on our planet[4] we may conclude that some 30,000 giant meteorites can have reached it since the Earth seems to be 4·5 thousand million years old, although 'geological time', that is, the record of the rocks, began only about 3 thousand million years since the oldest rocks known were implaced in the continental nuclei, or in the past 3×10^9 years or so. This supposes that the overall rate of fall was practically the same during this period as that assumed for 500 million years. If we admit a uniform distribution for the impacts of giant meteorites on the Earth's surface (about 5×10^8 km²), there may have been one impact about every 17,000 km², or, lineally, a crater-centre roughly every 130 km. Of course, uniform distribution is illusory, and one must expect that the craters would group in clusters with many consequent overlappings.

Geologists argue strongly against such a wealth of meteoritic features on the ground that well-established cosmic scars are rare. The answer to this is that at least 70 per cent of the missiles may have fallen in the oceans and that the majority of the remaining 30 per cent may lie buried under younger geological strata, or have been eradicated by erosion and tectonic movements, or distorted by overlappings and foldings. In addition, the criteria used to identify meteoritic structures have not the absolute character that is attributed to them, with the result that many features, actually ascribed to volcanic activity, may well be of meteoritic origin.

Meteoritics is a young science. Only since around 1945 has extensive research been undertaken. The results of field research have been spectacular. More and more geological features of possible or probable meteoritic origin have been found with diameters ranging from 10 to 20, 200 and even up to 450 km (ref. 5). It is true that many conclusions arrived at are still controversial, but we are only at the 'beginning'.

The discovery of possible or probable meteoritic structures of huge diameter raises the question of possible cosmic catastrophes. Can the Earth's movements have been disturbed by impacts of giant meteorites? If so, in which conditions and to what extent? Several geophysicists have lately directed attention to this problem, but, to my knowledge, no satisfactory mathematical study on this subject seems ever to have been published.

Indisputably, there exists a cosmic body of given mass which, on impact at a known speed, is able to shift the polar axis. This is explicitly recognized by Laplace in his *Exposition du Système du Monde*, in which he describes vividly the devastating results of such an encounter.

If m is the mass of a cosmic body, V its speed on impact, M the mass of the Earth ($= 6 \times 10^{27}$ g), R the equatorial radius ($=$ 6,370 km) and ω the Earth's angular velocity ($R.\omega = \frac{40,000}{86,400}$ km/sec), the angle α of shifting of the polar axis is given by the equation:

$$\frac{x}{100} \times \frac{1}{2} m V^2 = 1{\cdot}6 \times M \times (R\omega)^2 \times \sin^2 \frac{\alpha}{2} \text{ (ergs)} \quad (1)$$

$\frac{x}{100}$ represents the percentage of the total kinetic energy (produced by the meteorite on impact) used for the shifting. Only the balance of energy is considered here and it is supposed that, after impact, the angular velocity of the Earth has not been altered ($\overline{OM} = \overline{OM'}$) (Fig. 1).

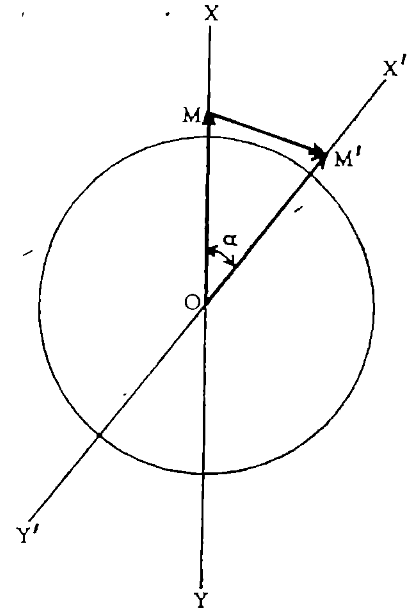

Fig. 1

XY and $X'Y'$ give the positions of the polar axis before and after impact.

The vector $\overline{MM'}$ represents the difference between $\overline{OM}$ and $\overline{OM'}$ and its value is:

$$2 \times \overline{OM} \times \sin\frac{\alpha}{2} \text{ or } 2.\omega.\sin\frac{\alpha}{2}$$

The quantity of energy used for the shift therefore is:

$$\frac{2}{5}.M.R^2 \times 4.\omega^2.\sin^2\frac{\alpha}{2} \text{ or } 1{\cdot}6 \times M \times (R\omega)^2 \times \sin^2\frac{\alpha}{2}$$

Innes has calculated the energy necessary for crater formation[3]:

$$E_c = 8{\cdot}44 \times 10^{12} \times D^2 \times d \text{ (ergs)}$$

in which D = diameter of crater in metres and d = density of impacted rock. If,

$$E_s = \frac{y}{100} \times \frac{1}{2} m V^2 \qquad (2)$$

and if V = 20 km/sec and d = 3, the value of α is easily obtained from (1) and (2):

$$\sin\frac{\alpha}{2} = 11 \times 10^{-13} \times \sqrt{\frac{x}{y} \times D^3}$$

The great difficulty is to assess acceptable values for x and y.

Innes gives y = 47 (ref. 3), adopting the results obtained in underground nuclear explosions[6]. For Öpik, y = 3 (ref. 7), but this value is too low in comparison with the results obtained by Johnson, Higgins and Violet[6]. It may be objected that Innes's figure is too high, for in meteoritic impacts the explosions do not occur in enclosed areas and the craters are hemispherical. In huge impacts able to shift the polar axis, one must expect that the energy required for such a shift is obtained mainly at the expense of that for crater forming and elastic effects. It may be assumed that the amount of energy used for shifting may be of the same magnitude as that spent in crater formation, if we do not take into consideration other possible phenomena, such as crust-slipping. Therefore, I propose as a working hypothesis the figure 30 for y and, in view of simplifying calculations in this work, I adopt:

$$x = y = 30$$

Then the following simple expressions may be used:

$$D = 0{\cdot}28 \times \sqrt[3]{m} \qquad m = 42{\cdot}2 \times D^3$$

$$\sin\frac{\alpha}{2} = 11 \times 10^{-13} \times \sqrt{D^3}$$

Further investigations will show to what extent the values of x and y must be modified.

Among the geological features accepted as being of probable meteoritic origin, the 'Vredefort Ring Structure' of South Africa, is outstanding. The question of its real diameter has not yet been settled. Daly[8] and Dietz[1,9] rate it at about 50 km. But Dietz stresses the point that the entire deformation reaches a diameter of 210 km (130 miles). Gilvarry[10] gives a diameter of 130 km. The central granitic core of the structure may well be the eroded root of an ancient dome, in which case, the original Vredefort feature could have been similar to the peculiar lunar craters with central uplift.

If we adopt 130 km, the structure may be the scar of an impacting body of 9·2 × 10[10] metric tons (V = 20 km/sec) shifting the polar axis by about 22″. If the diameter is 210 km, the mass of the missile was 3·9 × 10[11] metric tons and the shifting was about 38″.

An asteroid of the size of Juno (diam. about 190 km) would shift the polar axis by 45′ (V = 20 km/sec) and produce a crater of about 3,300 km in diameter. This is consistent with Gilvarry's hypothesis on the meteoritic origin of the oceanic basins[10].

It should be borne in mind that the above considerations do not take into account the possible 'slipping' of the lithosphere and the upper mantle on the underlying 'plastic layer', on meteoritic impact. This phenomenon would combine with the shifting of the polar axis and the energy required for it would certainly have to be deducted from that used for the shifting. There are good reasons for believing that this 'slipping' may well reach important values.

To conclude, I realize that my working hypothesis can only be the starting point of further investigations and that it involves many important geological and geophysical problems with far-reaching results. In the light of the actual known facts and the field research in progress, I feel confident that features of probable meteoritic origin, having disturbed our planet's movements, have already been found and that others are in progress of identification.

I thank Dr. D. Belorisky, of the Observatory of Marseilles, who helped me with astronomical aspects of this work.

May I compliment Colonel Gallant on his interesting communication. His central thesis that giant meteorite impacts are capable of disturbing the Earth's polar axis of rotation may well be correct. However, I would like to take this opportunity to comment on some other subjects raised by his paper.

I differ from most other geologists in assigning an important role to meteorite impacts. Based on the shock criterion of shatter-coning alone, I[1] have recognized about a dozen ancient geological structures which appear to be bona fide 'astroblemes' (star-wounds). But as a marine geologist I cannot believe that ocean basin features bear any close resemblance to those on the Moon as Chenoweth[2] has written. Neither can I accept the view that ocean basins are simply giant meteorite craters as Gilvarry[3], Harrison[4] and now Gallant suggest.

I have indulged in this speculation myself[5], but with the more conservative approach that large impacts might have fractured the Earth's primeval sialic crust in 'pre-geological' time (that is, pre-rock record but post-Earth, or between 3·0 and 4·5 thousand million years ago). I suggested that the shattered fragments then may have completely rearranged themselves in what we now observe as the continents and the ocean basins. Under this scheme, the early impacts would only account for the discontinuity of the sialic crust and not the present shape or morphology of ocean basins. (Nearly all geologists, including myself, will dismiss out of hand the suggestion that continental slopes are crater walls, that the marginal mountains are explosion debris, etc. Geological evidence points quite clearly to the development of ocean basins by slow evolution rather than catastrophic birth.) This idea still seems to me to have as much merit as, for example, another better-known catastrophic hypothesis—the breaking up of an initial crust by the Fisher–Darwin hypothesis of pulling the Moon out of the Pacific. If the Moon was cosmically bombarded, certainly it is reasonable to suspect that the Earth was similarly bombarded at some early time. But now I am inclined to accept a cold accretion model for the Earth under which proto-Earth had no sialic crust at all as we now know it. The water, the air and the crust probably are all secondary, squeezed out of the mantle by processes related to thermal convection circulation as evidenced by sea-floor spreading[1]. Accordingly, early Earth impacts would have encountered no crust to fragment.

The diameter of the hypothetical Vredefort Ring[6] crater is more definable than Colonel Gallant suggests. The 40 km across central plug of Old Granite must define the crater's true diameter (that is, diameter below original ground-level). Using Baldwin's (in the press) scaling factor for the original apparent diameter (from the top of one rubble rim to the opposite rubble rim), the crater would have been 48 km across. My figure of 210 km for the limit of deformation refers to folding far outside

PHYSICS DEPARTMENTAL L

of the crater *per se*. This figure was taken from Bishopp[7], but he recently[8] indicated that he now considers this figure as extravagant.

Gallant suggests that, in the absence of erosion, the Earth's surface would look like the Moon's crater-pocked face. I believe that geologists can state almost categorically that our geological maps do not permit this interpretation even in the shield regions where the basement complex is not obscured by sedimentary strata. Structures that can be interpreted by any stretch of the imagination as eroded impact craters are rather uncommon. Doubtless, we will find many more impact sites than are now recognized; but nothing comparable to the Moon.

Let us turn now to the question of the lunar maria or 'seas'. These do bear some resemblance to ocean basins in that they are depressed regions lined with dark rock; and although even Mare Imbrium is only the size of Texas, maria are, like ocean basins, dominating structures. Among those of us who consider maria as simply giant lunar impact craters, it might seem that we would extend this impact rationale to ocean basins; but I do not think it can be.

My reasoning concerning why the Earth's surface structures are fundamentally different from those of the Moon, without going into detail, is as follows. The primary diastrophic force, including the origin of ocean basins, is the thermal convection circulation in the Earth's mantle. Similar convection seems to be absent in the Moon, probably because of its comparatively small size. This I conclude from the simple observation that the lunar craters and maria, although mostly extremely old, do not reveal any significant tectonic distortion. On the Earth, they would have been compressed and thrust beyond all recognition.

The Moon must be a virtually crustless and coreless body. This agrees with the common assumption that the Moon is a primeval body resembling the early Earth and with a composition like that of a stony meteorite. The composition of tektites have a bearing on this subject since they may come from the Moon. Those who deny this origin rely as a main argument on the high silica and alkali content of tektites which is unlike that of stony meteorites. Here I would like to insert a *caveat*: magmatic differentiation well may have occurred in connexion with the evident outpourings of magma on the lunar surface. A welded tuff surface differentiate of this magmatism would likely be of rhyolitic composition which would closely resemble that of tektites.

The lunar maria appear to be filled with large saucer-shaped bodies of solidified magma rather than a series of thin lava flows. The rills and serpentine ridges suggest this, as they can be most easily explained by the contractional and compressional movements of a thick cooling magma. If so, they may be like extrusive lopoliths. Most geologists consider lopoliths as intrusive bodies, but some of us believe that many of them are extrusive (for example, Hamilton[9]).

It seems to me that we might look to lopoliths as possible terrestrial analogues of lunar maria. I have recently attempted this interpretation for the Sudbury lopolith and surrounding structure in Ontario[10]. I believe it to be an astrobleme involving an impact energy of about 3×10^{29} ergs, or twice the size of the Vredefort event. The Sudbury structure is my candidate for a maria-like feature on the Earth, rather than the ocean basins.

In conclusion, I believe that geologists are indeed guilty of looking down all of the time, when sometimes we should be looking up. On the other hand, the geological position of relying on conventional tectonic, plutonic and volcanic explanations is not arbitrary but well founded.

RATE OF FLOTATION IN A HALLIMOND TUBE

By DR. C. W. NUTT, DR. M. KEMP and J. WESTON
Department of Chemical Engineering, University of Birmingham

THE flotation behaviour of small quantities of a mineral can be determined in the laboratory by means of the Hallimond technique[1–4]. It is usual to design the experiment so that the results can be expressed as a percentage of the original mineral which is recovered by flotation after an arbitrary time interval. The time selected is generally between 1 and 5 min and is usually of sufficient duration to ensure that all the floatable material of the sample has been recovered.

However, if it is desired to investigate quantitatively the relation between flotation and variables such as collector concentration or parameters such as degree of adsorption of collector reagent, it seems preferable to arrange the experimental procedure so that the results can be expressed as a rate of flotation. Thus a flotation time shorter than that required for complete recovery of all the floatable material is necessary. To use the technique successfully in this quantitative fashion, it is then necessary to understand the importance, or otherwise, of operating variables such as gas flow rate, size of mineral bed and flotation time, and to know their effects on the observed flotation rate. No investigations of these aspects of the Hallimond technique are recorded in the literature, although Hallimond[4] noted that the gas flow rate should be enough to stir the bed, and such that the bubbles followed one another up the tube at intervals of 0·75 in. However, Fuerstenau[5] has shown that for a laboratory flotation tube with a stirred mineral bed, the amount of mineral recovered increases linearly with time, at constant gas flow rate, until recovery is almost complete, and that the recovery rate during this period of time is proportional to gas flow rate. The object of the experiments reported here was therefore to investigate these problems when the conventional Hallimond technique is used for the measurement of flotation rates.

The mineral used was beryl, crushed and dry sieved to a size range between 100 and 300 B.S.S. mesh size. It was pre-treated by standing in 1 per cent cold aqueous hydrofluoric acid (10 ml./mineral) for 0·5 h with occasional stirring, then washed with distilled water until the conductivity of the washing water was unchanged by contact with the mineral, and finally dried at 70° C overnight.

The desired weight of mineral (0·35–0·65 g) was then contacted with 65 ml. of a solution of the collector reagent for 30 min, with occasional shaking. The collector used

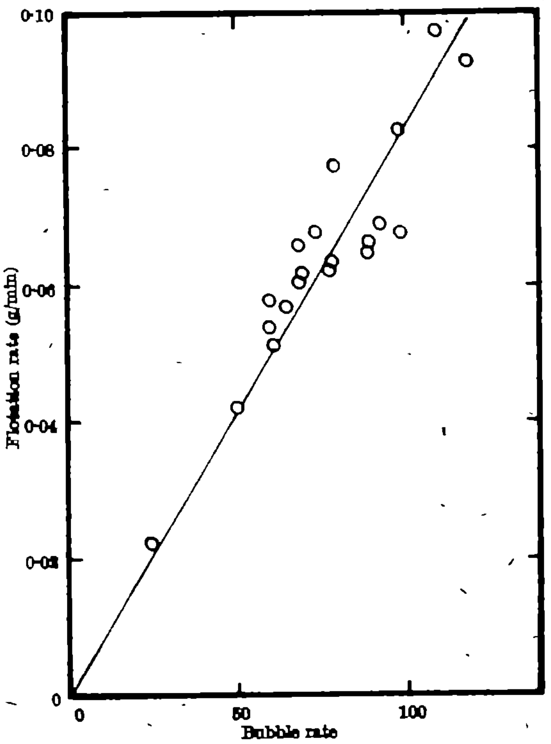

Fig. 1. Influence of gas flow rate on the rate of flotation

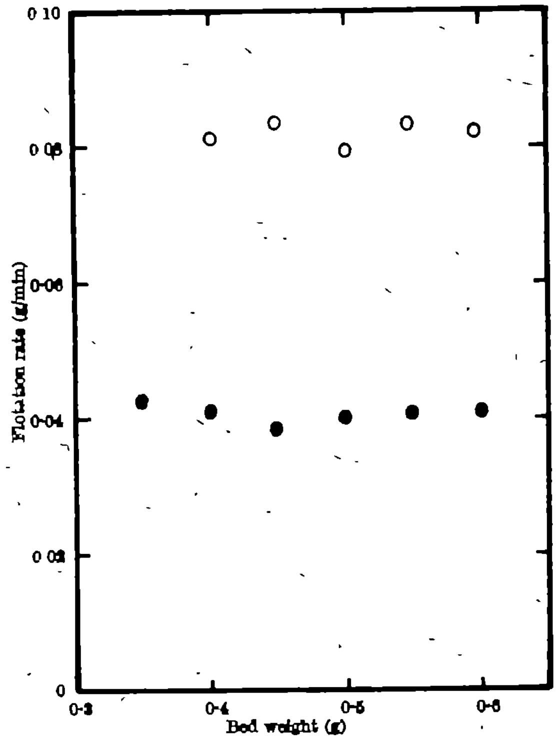

Fig. 2. Effect of mineral bed weight on rate of flotation

was 'Aero-promotor 824', at a concentration of 0·04 g/l., and hydrochloric acid was used to adjust the pH to the desired value. The slurry was then transferred to a Hallimond tube similar to that described by Sutherland and Wark[8], and air bubbled through at a steady rate. The same Hallimond tube was used for all the measurements.

In the first series of measurements, mineral beds of 0·50 g were used with gas flow rates between 25 and 120 bubbles per min. Flotation was continued until only about 0·1 g of the bed remained. Experiments involving flotation of the last 0·1 g of bed gave results which were difficult to reproduce because of the difficulty of regulating and measuring the bubble rate in these final stages. The results, reproduced in Fig. 1, show that within experimental error, the rate of flotation was directly proportional to the bubble rate.

In a second series of measurements, various bed weights (0·35–0·65 g) were used with bubble rates controlled within the range 80–100 bubbles/min. The observed rates of flotation were multiplied by (80/actual bubble rate) to give the flotation rate corresponding to a gas rate of 80 bubbles/min. Results for two series of measurements at different pH's are shown in Fig. 2 and indicate that the flotation rates are independent of bed size, over the range

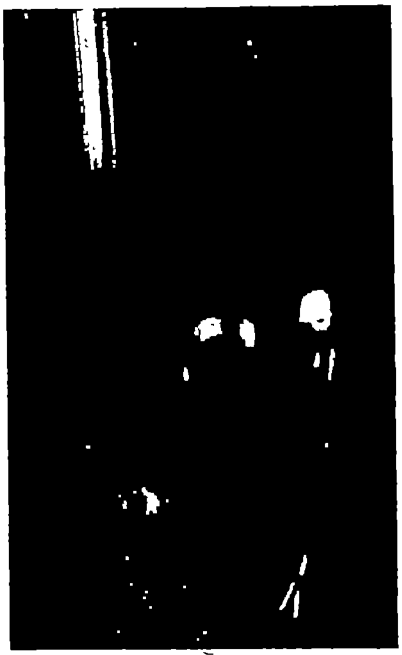

Fig. 3. Formation of a normal size bubble at the surface of the mineral bed in a Hallimond tube. The streaks on the underside of the bubble are formed by mineral particles being shed from the bubble

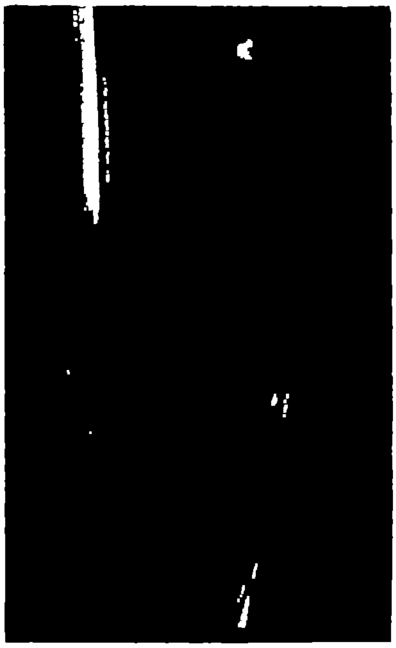

Fig. 4. Small heavily loaded bubble released shortly after a normal size bubble. Such small bubbles were always completely covered with mineral, so that they rose as 'solid' spheres without circulation of the gas within the bubble, and without formation of new interface at the front of the bubble. The normal bubbles were loaded only at the rear

used. Similar results were obtained in several other series of experiments using beryl pre-treated and conditioned in different ways.

In another series of measurements the influence of mineral size distribution was investigated. The beryl sample was separated by dry sieving to obtain the +300 −200, +200−170, +170−150, +150−100 fractions. Flotation rates, using the preceding technique, were the same for all samples, within experimental error.

Thus, for these systems, flotation rates can be compared by this modification of Hallimond procedure, providing the gas flow rate is accurately recorded; close control of the initial size of the mineral bed is not necessary. It is concluded that, for a given system, the mineral load carried by each bubble is the same, regardless of the rate of formation of the bubbles or depth of the bed. Measurement of the rate of flotation of a mineral by this procedure thus provides a quantitative measure of the floatability of the mineral, and the method has been successfully used in an extensive study of the flotation of beryl, which will be described elsewhere.

However, for the most readily floatable samples, some discrepancies were observed. Systems with flotation rates larger than 0·15 g/min at 80 bubbles/min gave results which were not accurately reproducible. Careful observation of these systems revealed the presence of two kinds of bubbles during flotation. In addition to the normal size, partly loaded bubbles (Fig. 3) were observed in all systems, and there were also a variable proportion of smaller bubbles (Fig. 4). These bubbles were always released from the bed immediately before or immediately after a normal bubble. Since their proportion was variable and could not be controlled, considerable variation resulted in the measured rate of flotation. Though the cause of the phenomena can only be a matter of speculation, it is suggested that the normal size bubble may be formed at the upper end of a continuous channel or void extending from the sintered disk to the upper boundary of the mineral bed. It is likely that such channels are less stable in beds of easily floatable mineral, and their collapse may lead to small pockets of air being trapped within the bed. The disturbance associated with the formation of a new channel would cause release of the pocket of air as a small bubble, at a point of time close to the moment of formation of the next normal bubble.

We thank the United Kingdom Atomic Energy Authority for financial support for the investigations and for the provision of mineral samples.

INTERACTION OF AMINO-ACIDS, PROTEINS AND AMINES WITH CHLORANIL

By Dr. J. B. BIRKS and Dr. M. A. SLIFKIN

The Physical Laboratories, University of Manchester

FOR several years there has been speculation about the possible role of charge-transfer complexing in different biological systems[1–4]. $\pi-\pi$ charge-transfer complexes, where the donated electron forming the complex is a π-electron, have been mainly considered. Less attention has been given to the possibility of $n-\pi$ charge-transfer complexes being formed, although many biological materials contain suitable lone-pair electrons.

One common acceptor which readily forms charge-transfer complexes is chloranil (tetrachloroquinone). $\pi-\pi$ complexes of the polycyclic aromatic hydrocarbons with chloranil have been studied by several authors[5–8]. $n-\pi$ complexes involving chloranil have also been observed[9–11]. Although chloranil does not occur in natural systems, its behaviour may be considered indicative of that of other quinones, such as ubiquinone, which are of biological interest.

In the present work the absorption spectra of mixed solutions of amino-acids and chloranil and of proteins and chloranil have been studied. It is observed that, on adding an amino-acid to a 10^{-3}–10^{-4} M solution of chloranil in 50 per cent aqueous ethanol buffered to a suitable *p*H, a change occurs in the solution spectrum. The absorption band *A* of chloranil at 295 nm is decreased and a new band, *B*, appears at longer wave-lengths. This behaviour is shown in Fig. 1. The position of band *B* is dependent on *p*H, varying between 380 nm and 330 nm as the *p*H of the solutions is varied between *p*H 4 and *p*H 12, but it appears to be independent of the nature of the amino-acid. Some absorption spectra of amino-acid–chloranil mixtures at various *p*H are shown in Fig. 2. Table 1 lists the amino-acids studied and the wave-lengths of maximum absorption of the new bands.

The effect is reversible. Increase in temperature causes the band *B* at 370 nm to decrease in intensity and the chloranil absorption band *A* at 295 nm to increase in intensity as shown in Fig. 3.

In alkali solution a small fraction of the chloranil is changed, probably to chloranilic acid[12]. Fig. 4 shows some spectra of new and old solutions of chloranil at different *p*H and some aqueous solutions of chloranilic acid at different *p*H. It is seen that the fraction of chloranil degraded is very small, the positions of the chloranilic acid absorption band at 330 nm are scarcely affected by the changes in *p*H. It is clear that chloranilic acid is not responsible for the effects observed in chloranil–amino-acid solutions.

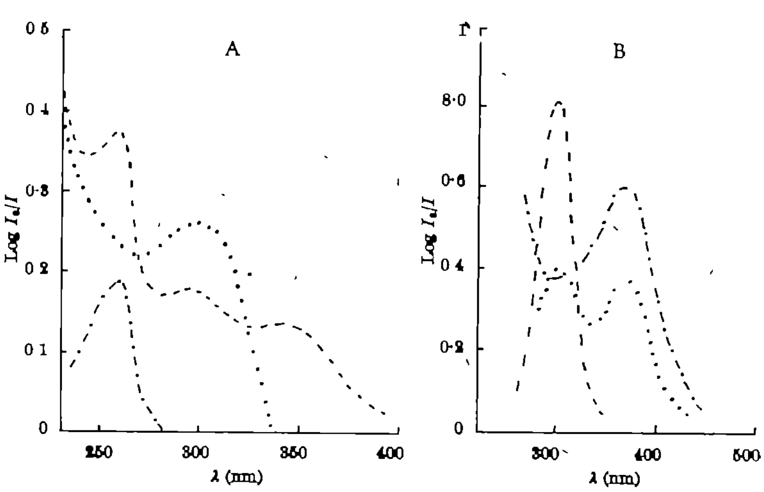

Fig. 1. Absorption spectra of: *A*, *a*, Phenylalanine ($1·06 \times 10^{-3}$ M) (— · —); *b*, chloranil ($2·27 \times 10^{-3}$ M) (· · ·); mixture of *a* and *b* (– – –); all in 50 per cent ethanol buffered to *p*H 7. *B*, chloranil (8×10^{-3} M) (– – –); plus glycine (10^{-3} M) (— · —); plus alanine (about 10^{-3} M) (· · ·); all in 50 per cent ethanol

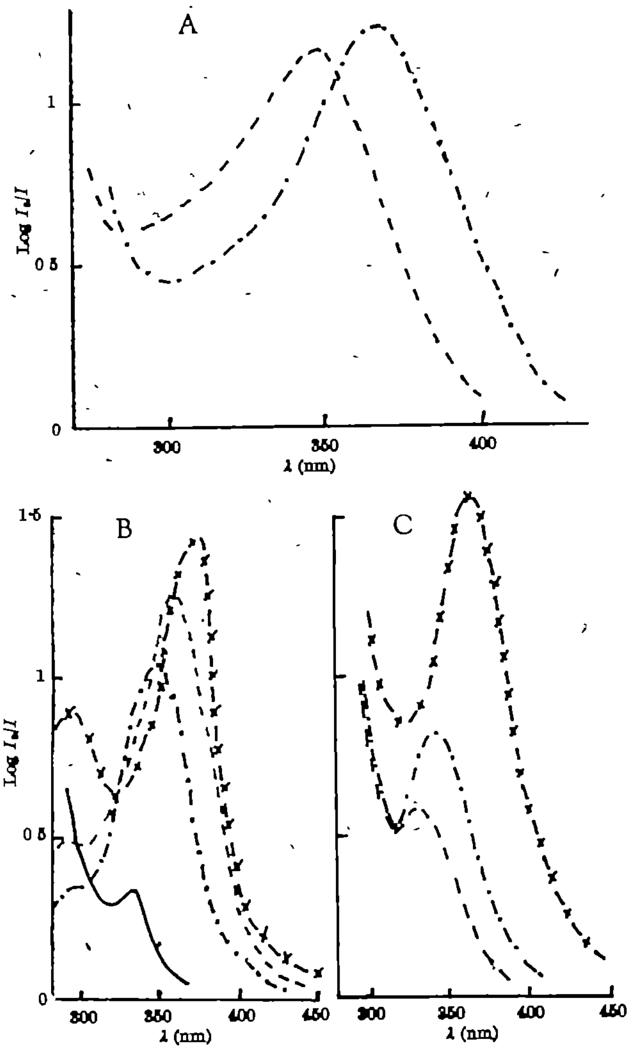

Fig. 2. Absorption spectra of: *A*, chloranil (about 2×10^{-4} M) and leucine (about 10^{-1} M) in 50 per cent ethanol buffered to *p*H 7 (—·—); chloranil (about 2×10^{-4} M) and glycine (about 10^{-1} M) in 50 per cent ethanol buffered to *p*H 9 (– – –). *B*, chloranil plus glycine in 50 per cent ethanol buffered to *p*H 7 (—×—); *p*H 9 (– – –); *p*H 11 (—·—); *p*H 13 (——). *C*, chloranil plus tryptophan in 50 per cent ethanol buffered to *p*H 7 (—×—); *p*H 9 (– – –); *p*H 11 (—·—)

The inverse concentration of amino-acid has been plotted against the inverse optical density of band *B*. An approximately linear relation is found corresponding to the Benesi–Hildebrand equation for 1 : 1 complexes[13], namely:

$$\frac{[b]\,l}{\log\frac{I_0}{I}} = \left(\frac{1}{K\varepsilon_c}\right)\left(\frac{1}{[a]}\right) + \left(\frac{1}{\varepsilon_c}\right), \text{ for } [a] \gg [b]$$

where $[a]$ and $[b]$ are the molar concentrations of the two components. K is the equilibrium constant of the complex given by:

$$K = \frac{[ab]}{[a-ab]\,[b-ab]}$$

where $[ab]$ is the molar concentration of the complex, l is the optical path length and ε_c is the molar extinction coefficient of the complex species. The values of the equilibrium constant K evaluated from the intercept and slope are listed in Table 2. K appears to decrease with increasing *p*H. Typical plots are shown in Fig. 5.

The absorption spectra of mixed solutions of proteins and chloranil in 50 per cent aqueous ethanol have also been studied. Typical results are shown in Fig. 6. Table 3 lists the positions of the new bands observed. The spectra of chloranil–protein mixtures are very similar to the spectra of chloranil–amino-acid mixtures except that, for a given *p*H, the position of the band *B* lies at shorter wave-length in the protein systems than in the amino-acid systems. Comparable weights of protein and amino-acid

* Poorly resolved.

in about 10^{-4} M solutions of chloranil give comparable optical changes. On adding alkali to solutions of protein and chloranil, a purplish precipitate is formed. The precipitates from a bovine-serum albumin–chloranil solution and a fibrinogen–chloranil solution are found to exhibit semi-conductor behaviour and a d.c. conductivity of 10^{13} Ω cm. This is in reasonable agreement with the data of Eley *et al.*[4], who also showed that a bovine-serum albumin complex behaved like a semi-conductor with a conductivity of about 10^{12} Ω cm.

Absorption spectra of mixed solutions of chloranil and amino-acid analogues have also been studied. Typical spectra are shown in Fig. 7. The spectrum of chloranil in acetic acid is similar to the spectrum of chloranil in different inert solvents[14]. On the other hand, the spectra of the various chloranil amino-compound mixtures are similar to those of the amino-acids and proteins. The new bands observed in these mixtures are also reversible, decreasing in intensity with increase in temperature. Solutions of these mixtures in 50 per cent aqueous ethanol exhibit only a new sharp band in the region of 350–420 nm (ref. 11), but in solutions in carbon tetrachloride an additional broad band, probably corresponding to the conventional charge-transfer band, is often observed at rather longer wave-lengths[18]. Anthranilic acid in carbon tetrachloride turns a bronze colour on adding chloranil, but the other amino-benzoic acids do not give any visible coloration in the presence of chloranil. The positions of these new absorption peaks and the *p*H of the solutions are tabulated in Table 4.

The absorption spectra of chloranil–amino-acid and chloranil–protein mixtures are very similar to those of chloranil–amine mixtures. It is concluded that the amino-groups in the amino-acids and proteins form *n*–π charge-transfer complexes with chloranil. The new band *B* has already been interpreted as being due to a red-shift of the chloranil band on complexing[11]. The studies reported here support this interpretation. The complex is probably formed by a lone-pair electron from the nitrogen in the amino group being donated to the chloranil. Although the normal charge-transfer band has not been observed in these amino-acid systems, it has been shown that some aliphatic amines show such a charge-transfer band in carbon tetrachloride but not in 50 per cent aqueous ethanol.

Booth and Boyland[15] found that various hydrocarbons form 1 : 1 complexes with purines in 50 per cent aqueous ethanol. It was later shown[16,17] that the infra-red spectra and crystal structure of these complexes are very similar to those exhibited by charge-transfer complexes. Booth and Boyland concluded, however, that these hydrocarbon–purine complexes could not be charge-transfer complexes because of the absence of the normal charge-transfer band. The present work suggests that charge-transfer complexes may be formed without the appearance of a typical charge-transfer absorption band.

Although the amino-acids exist as dipolar ions in neutral solution, in the presence of chloranil they behave as though they still possess an un-ionized amino group. This raises the question as to whether the equilibrium constants given in Table 2 are correct. If the amino-acids exist in both ionized and un-ionized form in the presence of chloranil, then the concentration of the amino-acid used to evaluate the equilibrium constant should be that of the un-ionized amino-acid.

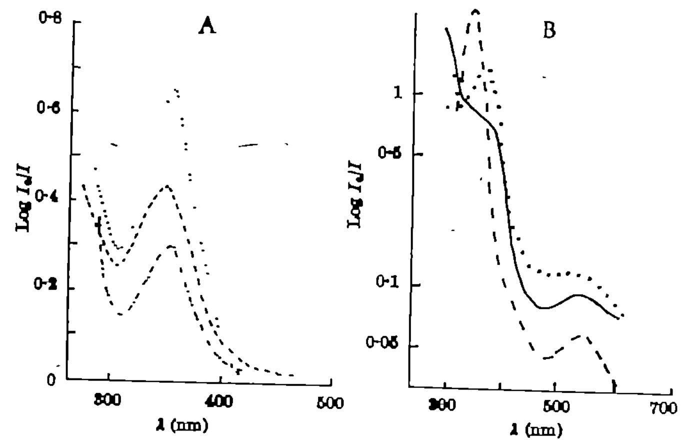

Fig. 6. Absorption spectra of: *A*, mixtures of chloranil and trypsin (···); horse serum albumin (– – –); γ-globulin (—·—); all in 50 per cent ethanol buffered to *p*H 8. *B*, mixture of chloranil and fibrinogen in 50 per cent ethanol buffered to *p*H 7 (——); *p*H 8 (···); *p*H 10 (– – –)

Increasing the *p*H of the solutions causes the band *B* to shift to shorter wave-lengths. If this band is the original chloranil band shifted to longer wave-length on complexing, this would indicate that at higher *p*H the complexes are weaker. Amino-groups are expected to be better electron donors in acid solution than in alkali solution. Table 2 also shows a decrease in the equilibrium constants of the complexes on increasing *p*H. The observation that comparable weights of protein and amino-acids produce similar changes in the spectrum of chloranil suggests that many of the amino-groups in the protein complex with the chloranil.

We thank Dr. F. J. W. Teale for helpful discussions. We also thank Mr. N. J. Dunning for the semi-conductivity measurements.

One of us (M. A. S.) wishes to acknowledge tenure of a D.S.I.R. research studentship and afterwards of a D.S.I.R. research fellowship.

ABSORPTION SPECTRA IN IRRADIATED WATER AND SOME SOLUTIONS

Absorption Spectra of 'Hydrated' Electron

IN studying the absorption spectra of various aqueous solutions after exposure to a pulse of 1·8-MeV electrons, we have discovered a broad transient absorption band extending from wave-lengths below 5000 Å to beyond the limit of the emulsion sensitivity at 8800 Å, and having a peak near 7000 Å. We believe that this band is due to the hydrated electron, the existence and properties of which were predicted by Platzman[1]. It was first observed (Fig. 1) in a de-aerated 0·5 molar solution of sodium carbonate, but has since been found with somewhat lower intensity in pure de-aerated water (Fig. 2). It is strong in solutions containing sodium sulphate, hydroxide or chloride, but is absent in sodium bicarbonate or formate. Solutions of lithium and potassium carbonate and chlorides also give some degree of enhancement. In each of the solutions referred to, and in pure water, essentially the same band appears, with small differences of detail which are probably not significant. We have found the band in neutral and in alkaline solutions, but if it is present at all in strongly acid solutions it is very weak. A low concentration of dissolved oxygen reduces the absorption.

The experimental arrangement consisted of a 6-cm long all-quartz cell with a thin window on one side through which the electron beam entered. A dose of some 4–10 k.rads was given in a 2-μsec pulse. The absorption spectrum was taken on a Hilger intermediate quartz spectrograph (*E*.486) using Kodak III. scientific plates and a spark light source with a time duration of some 4 μsec (ref. 2). When the spark was triggered simultaneously with the electron pulse the absorption band illustrated in Fig. 1 was present. More than half this absorption had vanished in a delayed spectrogram taken 10 μsec after the pulse, but traces were still detectable for more than 20 μsec.

Transient absorption in 0 5 M aqueous solution of sodium carbonate. *a*, Densitometer trace of part of a spectrogram taken through unirradiated solution (the peaks are due to the sensitizers in the emulsion); *b*, densitometer trace of same part of spectrum taken simultaneously with a 2 µsec electron pulse (*c*. 4 k.rads); *c*, difference curve

The presence of solvated electrons in solutions of the alkali metals in liquid ammonia, in methylamine or in ethylamine has been recognized for many years[2]. Evidence for the existence of trapped electrons in these liquids is provided by the form of their optical absorption spectra[4] as well as by their high conductance[5], paramagnetic susceptibility[6] and electron spin resonance spectrum[6,7]. The optical absorption spectrum of the solvated electron in liquid ammonia is a broad band with a peak at 14,500 Å (ref. 3) and in pure methylamine it is a broad band with a peak at 7000 Å (ref. 8). In mixtures of methylamine with ammonia the peak at 7000 Å appears when the percentage of methylamine in the mixture exceeds 70 per cent[9].

We prepared aqueous solutions of ammonia of various concentrations, and observed the absorption spectra when these were exposed to a pulse of some 10 k.rads of 1·8 MeV electrons. For ammonia concentrations of 1·2 molar or lower we found the absorption band characteristic of water, but in a 12 molar solution the absorption increased continuously to the limit of the emulsion sensitivity at 8800 Å, without showing a peak (Fig. 3). It resembled closely the tail of the absorption spectrum of solvated electrons in liquid ammonia, although the proportion of ammonia to water molecules in our solution was only about 1 : 4.

Since the transient spectrum we have observed is produced by the irradiation of pure de-aerated water, is affected in intensity but not in character by the presence of various alkali metal ions and various anions, is suppressed by oxygen, is of short life, and is a broad band resembling the spectrum of the solvated electron in liquid ammonia, methylamine and ethylamine, we believe that it is due to the electron trapped in a similar manner in water, as predicted by Platzman[1].

The difference curves in Figs. 1–3 were obtained after bringing the two densitometer traces arbitrarily into coincidence at 5000 Å, where the emulsion sensitivity has a minimum. This expedient was adopted in order to

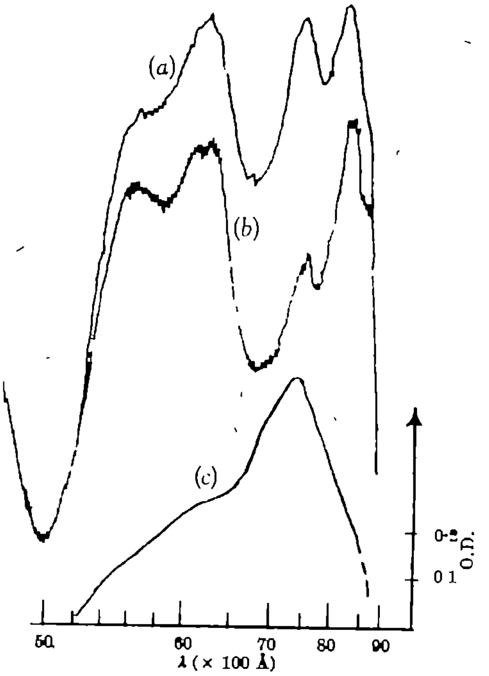

Fig. 2. Transient absorption in pure de-aerated water. *a*, unirradiated water; *b*, simultaneous with 2-µsec electron pulse (*c*. 10 k.rads); *c*, difference curve

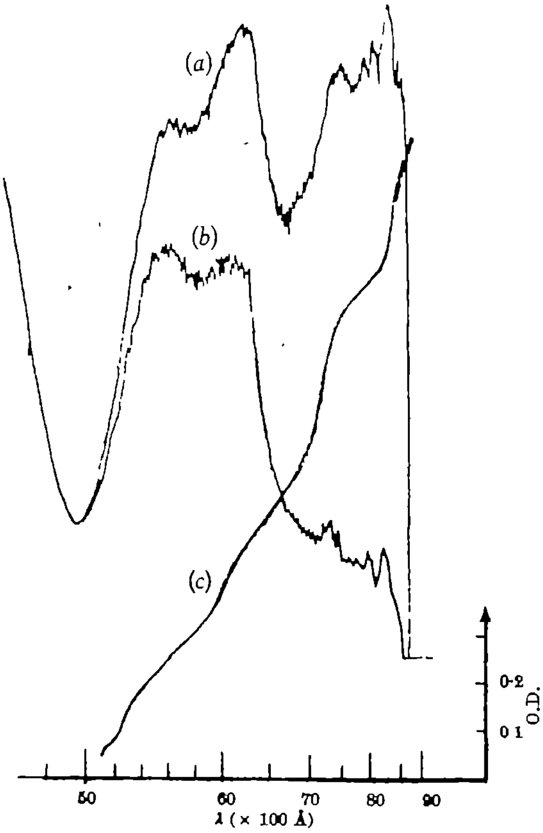

Fig. 3. Transient absorption in 12 M solution of ammonia in water. *a*, unirradiated solution; *b*, simultaneous with 2-µsec electron pulse (*c*. 10 k.rads); *c*, difference curve

eliminate from the comparisons small variations in total light output between successive sparks. The absorption band has, however, a long tail which extends throughout the visible region of the spectrum.

We thank Dr. L. H. Gray, Dr. G. E. Adams and Dr. R. L. Platzman for criticisms and suggestions.

Optical Absorptions in Irradiated Water

Boag and Hart (preceding communication) have observed a short-lived optical absorption band in water and various aqueous solutions irradiated with 2 μsec pulses of fast electron radiation. They attribute this band, which has a peak at ~ 7000 Å, to the presence of 'hydrated' electrons. In their experiments a light flash and spectrograph were used to produce a photograph of the absorption spectrum. I have used the complementary technique with a steady light source and photocell to obtain a cathode-ray oscilloscope trace showing the absorption as a function of time at any chosen wave-length. In this way more detailed information is obtained concerning the lifetimes of short-lived species but absorption spectra can be investigated only by repeated measurements at a series of wave-lengths. The apparatus has already been described and reference made to the existence of optical absorption in pure water[1,2].

The present communication describes some of my observations with water in more detail. The results obtained were the same in distilled water and in water redistilled from alkaline permanganate in silica. Also, the irradiation vessel was long enough to prevent irradiation of the optical end-plates by scattered electrons from the beam. It is believed, therefore, that the results can only be due to radiation effects in water and their modification by the presence of dissolved gases. De-aerated water was produced by bubbling argon for 24 h in the irradiation apparatus immediately before the exposure. The dose per pulse was ~ 5,000 rads and the optical path in the irradiated volume ~ 2 cm.

During the 2-μsec pulse Čerenkov light was produced in the water and under some conditions increased the apparent transmission above 100 per cent. This is shown in Fig. 1 for aerated water at 3100 Å. In general, the deflexion during the pulse is a combination of loss in light due to absorbing substances produced by the radiation and gain in light from the Čerenkov effect. The true drop in transmission can then be obtained by comparing traces obtained with the lamp shutter open and closed, the latter giving the amplitude of the Čerenkov light alone. In the case of Fig. 1 identical deflexions were obtained, thus showing the absence of detectable amounts of absorbing substances during the pulse itself. The blurring and brightness modulation on the trace are due to electrical interference from the linear accelerator, but its general shape shows that the beam intensity was reasonably constant during the pulse. Immediately after the pulse the transmission is 99 per cent and it then returns slowly towards 100 per cent, showing the presence of transient absorbing substances. This was clearer with increased amplifier gain[1] and has been found to consist of two components with half-times of ~ 10 μsec and ~ 1,500 μsec. These two components were only present in the ultra-violet beyond 3500 Å and measurements at a series of wave-lengths showed that they had similar (but not identical) absorption bands. No change in the faster component was produced by oxygenating or by de-aerating but the slower component was enhanced by oxygenating and was absent in de-aerated samples. At 5430 Å the Čerenkov radiation was much weaker and with aerated water a rapid drop in optical transmission to 95·8 per cent (after correction for Čerenkov light) occurred at the beginning of the pulse followed by recovery to 100 per cent immediately after the pulse. This is shown in Fig. 2. In de-aerated water at this wave-length the drop in transmission was five times greater and had a slower rise and fall (Fig. 3). In oxygenated water using increased amplifier gain it was found to be five times smaller and had the same flat base as in the aerated samples. The

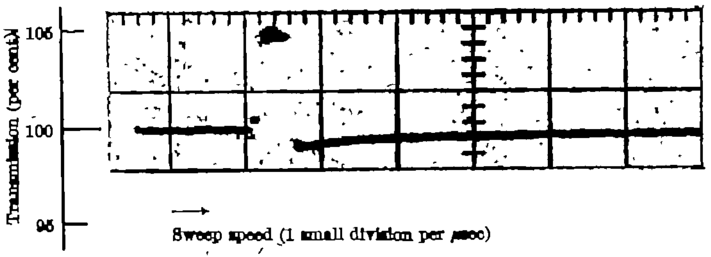

Fig. 1. Optical transmission of aerated water at 3100 Å before, during and after a 2 μsec electron pulse. Čerenkov emission occurs during the pulse and a small optical absorption immediately afterwards

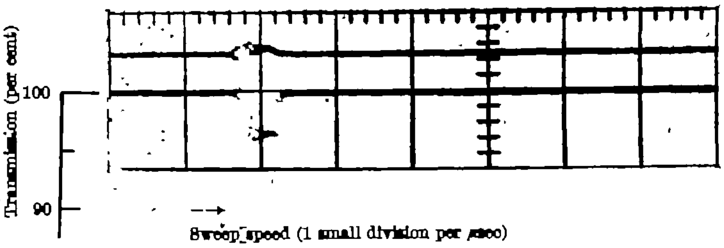

Fig. 2. Lower trace: optical transmission of aerated water at 5430 Å before, during and after a 2 μsec electron pulse. Upper trace: separate sweep with light shutter closed showing Čerenkov emission only

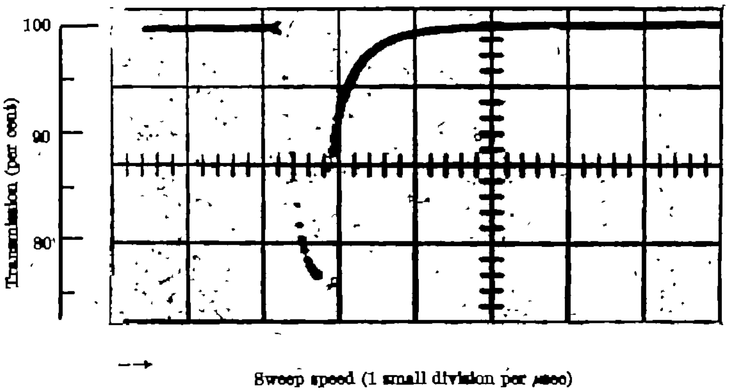

Fig. 3. Optical transmission of de-aerated water at 5430 Å before, during and after a 2 μsec electron pulse

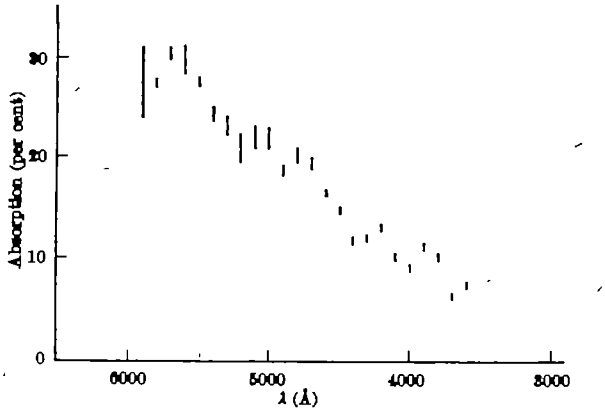

Fig. 4. Absorption spectrum of de-aerated water immediately before the end of a 2 μsec electron pulse

absorption spectrum was independent of dissolved oxygen (apart from amplitude) and is shown in Fig. 4 for de-aerated water. The vertical lines are equivalent to 1 mm on the oscilloscope screen. They do not include errors due to variation of dose from pulse to pulse but these were usually small as was shown by separate measurements on individual pulses with an integrating secondary emission chamber. The spectrum is not inconsistent with the band observed by Boag and Hart and may therefore be due to the same absorbing substance. Lack of photocell sensitivity made observations difficult beyond 6000 Å and the position of the absorption maximum could not therefore be established.

These results suggest that an absorbing substance with the spectrum of Fig. 4 is produced at a rate proportional to the initial slope of Fig. 3 (– 18 per cent per μsec) when water is irradiated with an ~5,000 rads pulse of fast electrons. If this substance does not react with dissolved carbon dioxide or nitrogen then it presumably reacts with oxygen to reach equilibrium concentrations corresponding to the 4·2 per cent drop in transmission shown in Fig. 2 in the case of air saturated water ($0·3 \times 10^{-3}$ molar oxygen) and the five times smaller drop observed in the case of oxygen saturated water ($1·4 \times 10^{-3}$ molar oxygen). From these figures the rate constant for the oxygen reaction can be calculated to be $1·5 \times 10^{10}$ l. mol^{-1} sec^{-1}. In de-aerated solution the recovery to 100 per cent after the pulse fits neither an inverse concentration plot nor an exponential. Thus removal of the substance in zero or very low oxygen concentration may occur by more than one reaction. Irradiation of 5×10^{-3} molar ferrous sulphate in 0·8 N sulphuric acid under the same conditions produced a drop in transmission at 3100 Å from 100 per cent to a steady value of 49 per cent after allowing 30 sec for the hydrogen peroxide reaction to go to completion. Comparison of this result with the initial slope of Fig. 3 gives a product of *G* value and extinction coefficient of 18,700 for the substance produced in water, taking *G* (Fe^{+++}) as 15·6, extinction coefficient (Fe^{+++}) as 2.100, and 2 μsec for the pulse-length.

DISULPHIDE—SULPHYDRYL EXCHANGE IN DOUGH

By DR. C. A. M. MAURITZEN and P. STEWART
Russell Grimwade School of Biochemistry, University of Melbourne

IT has long been recognized that the protein complex, gluten, is the principal component responsible for the visco-elastic properties of doughs made from wheat flour. Sullivan *et al.*[1] suggested that bromate or persulphate, the mild oxidizing agents used as dough 'improvers' by the baking industry, exert their action by causing the formation of additional protein disulphide bonds. More recently, Goldstein[2] examined the effect of oxidizing and sulphydryl blocking reagents on the rheological properties of dough and postulated an interchange of disulphide and sulphydryl groups which would account for the relaxation with time of induced strains in doughs and the failure of these strains to relax when dough had been treated with such reagents. Frater *et al.*[3,4] and Mecham[5] have elaborated this theory and have postulated that the strength of a dough is related to the number of intermolecular disulphide bonds in gluten and that relaxation of strains in dough is a function of the rate at which 'available' or 'accessible' sulphydryl groups exchange with disulphide bonds.

The experimental evidence for such sulphydryl–disulphide interchange in dough was lacking until recently, when McDermott and Pace[6] made use of the hydroxyproline-content of thiolated gelatin to demonstrate that, on mixing, thiolated gelatin becomes bound to gluten proteins.

In order to examine the chemical interactions which have taken place it is useful to separate the components of dough after mixing. It was felt undesirable, for several reasons, to use exhaustive solvent extractions for this purpose, and therefore a technique of dough fractionation which involved no extractants or diluents was developed. The dough, after mixing and resting, was subjected to preparative ultracentrifugation for 1 h at 30,000 r.p.m. (Spinco model *L*, head 30) and 30° C. This process was found to resolve dough into 5–7 distinct layers depending on the previous dough treatment. The main layers are, in ascending order of sedimentation rate, a lipid layer, a viscous, amber, dough liquor, a damaged-starch layer, a main gluten layer and a granular starch layer. The chemical composition of the principal layers is to be reported elsewhere.

It should be pointed out that only one of these layers, namely, dough liquor, which contains the components of dough soluble in dilute salt-solution, can be directly obtained uncontaminated by other layers. The remaining layers all contain dough liquor to a varying extent.

An examination of the incorporation of ^{35}S-cysteine and ^{14}C-leucine into the proteins of dough has been made by following the recovery of labelled compound in dough liquor, and the results are summarized in Table 1.

50 g of wheat flour were mixed with 31·7 ml. of salt solution containing the appropriate concentration of

Table 1. PERCENTAGE OF ADDED COUNTS IN FRACTIONS

* 1 μmole ^{14}C-1-DL leucine. † 0·5 μmole ^{35}S-cysteine.

labelled compound. After resting, the dough liquor was separated by ultracentrifugation.

Preliminary experiments with ^{14}C-labelled leucine established that the isotope was present in dialysable form in the dough liquor in almost the expected concentration, indicating that only 4 per cent of ^{14}C-leucine had become bound to the non-dialysable components of dough (Table 1, Exp. I).

When 0·5 μmole of ^{35}S-cysteine (52 mc./m.mole) was added to dough during mixing, 24 per cent of the added isotope was bound to gluten and 11 per cent to the soluble proteins of dough liquor (Exp. II).

Dialysis of a suspension of the gluten or soluble proteins against 8 M urea containing 0·5 M sodium chloride, did not remove the isotope. It was removed, however, by dialysis against 8 M urea containing 0·25 M sodium sulphite, or by performic acid oxidation, suggesting that the ^{35}S-cysteine was bound to protein through disulphide–sulphydryl interchange according to reaction 1, or (after oxidation to cystine) by 2, or by oxidation via reaction 3:

$$\text{Protein S—S—protein} + \text{Cy}\overset{*}{\text{S}}\text{H} \rightleftharpoons \text{Protein S—}\overset{*}{\text{S}}\text{Cy} + \text{Protein SH} \qquad (1)$$

$$\text{Protein SH} + \text{Cy}\overset{*}{\text{S}}\overset{*}{\text{S}}\text{Cy} \rightleftharpoons \text{Protein }\overset{*}{\text{S}}\text{—}\overset{*}{\text{S}}\text{—Cy} + \text{Cy}\overset{*}{\text{S}}\text{H} \quad \text{(Hird and Frater}^{7}\text{)} \qquad (2)$$

$$\text{Protein SH} + \text{Cy}\overset{*}{\text{S}}\text{H} + \tfrac{1}{2}\text{O}_2 \rightarrow \text{Protein S—}\overset{*}{\text{S}}\text{Cy} + \text{H}_2\text{O} \qquad (3)$$

Half the dialysable radioactivity of dough liquor was present as phosphotungstic acid-precipitable material and appeared to be either cystine or other low molecular weight disulphides, suggesting that some oxidation of cysteine to cystine does occur.

The disulphide content of 50 g of flour was found by amperometric titration with methyl mercuric nitrate to be 480 μmoles, the total sulphydryl 63 μmoles, and the dialysable sulphydryl groups (both endogenous and that added) initially present was calculated to be 12 μmoles; thus, despite the high ratio (nearly 40 : 1) of protein disulphide to dialysable sulphydryl groups, the reaction does not go to completion.

The reaction of ^{35}S-cysteine with dough proteins appears to be far from equilibrium since the reaction constant (calculated for reaction (1)) was found to increase linearly with increasing cysteine-levels. Furthermore, increased incorporation of the isotope into gluten, but not the dough liquor proteins, occurred with increased times of both mixing and resting (Exps. III and IV).

As indicated by reaction 3, it is possible that cysteine may be bound to gluten by oxidative formation of disulphide bonds with protein sulphydryl groups. However, mixing under nitrogen resulted in a greater incorporation into the proteins of dough. If incorporation were oxidative in nature, less, not more, ^{35}S-cysteine would be bound to protein under these conditions (Exp. V). While oxidative incorporation remains a possibility, disulphide–sulphydryl interchange appears to play the major part. The relative importance of reactions 2 and 3 cannot easily be determined, but ^{35}S-cystine is incorporated to a lesser extent than cysteine.

We thank the Wheat Industry Research Council for financial assistance.

UNEQUAL BILATERAL SODIUM EXCRETION IN SHEEP WITH AN EXTERIORIZED URETER

By B. D. STACY and A. H. BROOK

Ian Clunies Ross Animal Research Laboratory, C.S.I.R.O., Prospect, New South Wales

A METHOD of chronic unilateral urinary diversion in the sheep by means of a cutaneous ureterostomy is being developed in this laboratory. The nine animals so far studied all showed the odd characteristic of excreting more sodium through the operated than the intact ureter, the magnitude of the effect being illustrated in Table 1. The excretion values in Table 1 were calculated from 24-h urine samples with the animals on a low sodium intake (about 20 m.equiv./day). Urine from the fistulated ureter (*U*) consistently contained more sodium than urine from the intact ureter and bladder (*B*); the ratio of excretion on the two sides (*U*/*B*) varied widely both within and between animals.

With the exception of two sheep (1780 and 1784) in Table 1, further observations on renal excretion were cut short by the intervention of permanent ureteral stricture. The two animals referred to were examined for several months after exteriorization of the ureter and the *U*/*B* ratio for sodium excretion in the late post-operative periods is shown in Fig. 1. Urine specimens (24 h) from the ureter and bladder were compared for sodium content. The points on the graph represent the average *U*/*B* ratio for the number of collections made during 10-day intervals. Fig. 1 shows that there was a distinct change in the *U*/*B* ratio with the lapse of time after the operation. Fluctuations in daily values were not so marked in the later periods, and the kidneys began to show a more equal excretion of sodium 3–4 months after ureteral surgery. Increasing the sodium intake by 200 m.equiv./day did not, as Fig. 1 shows, affect the *U*/*B* ratio for sodium excretion.

The cause of the divergent handling of sodium by the two kidneys is unknown and is not to be found in the more obvious processes that might feasibly affect the appearance of sodium in urine. During the time the sheep were exhibiting the effect shown in Fig. 1, there was nothing to suggest from other observations that the kidneys were grossly different. Functional comparison of the separate kidneys showed that they were similar with respect to glomerular filtration (creatinine clearance), effective renal plasma flow, tubular secretion of *p*-aminohippuric acid, urea clearance, potassium and hydrogen ion excretion and the ability to elaborate hypertonic urine. The dis-

* Further data in Fig. 1. † Highest value excluded.

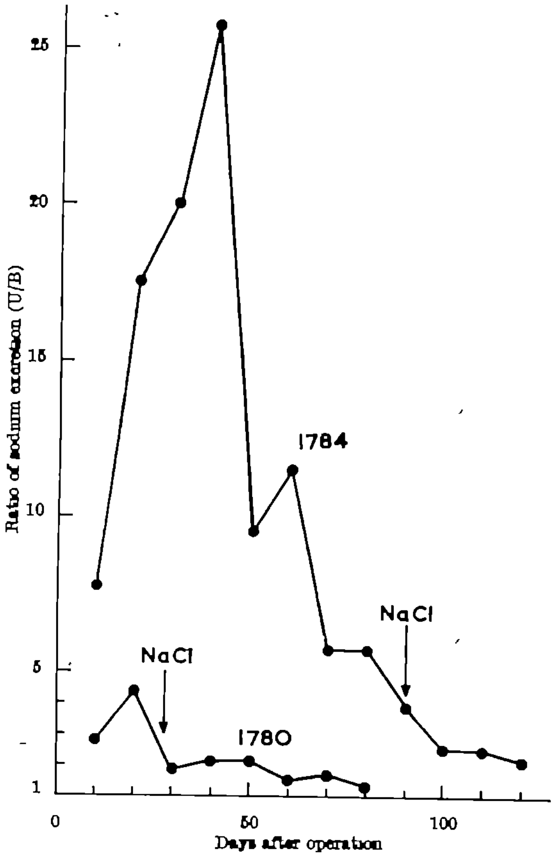

Fig. 1. Ratio of sodium excretion by the separate kidneys in two sheep (1780 and 1784) with explanted right ureters. Values were calculated from daily urine samples; sodium intake increased from 20 to 200 m.equiv./day at the points indicated

proportionate excretion of sodium occurred when the urine was sterile and free of protein.

In the first few days after the operation, all the animals except one experienced occasions when urine-flow from the fistulated ureter was temporarily obstructed, often by small blood clots, for an hour or more. The effect of such obstruction on electrolyte excretion in the sheep is unknown. Transient ureteral occlusion in the dog does not cause an increase in sodium on the obstructed side[1], although clinical studies in man[2] have revealed abnormal renal losses of sodium and water following the relief of complete obstruction of the urinary tract.

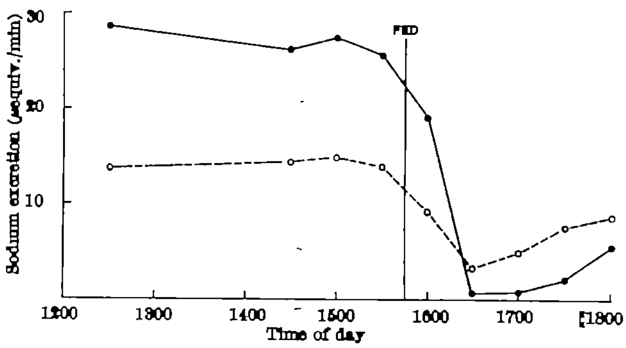

Fig. 2. Postprandial decrease in sodium excretion showing comparison of samples collected from the exteriorized ureter and the bladder; sodium intake 200 m.equiv./day (sheep 1780). ○, Bladder; ●, ureter

Despite the chronic nature of the effect, the kidney on the side of the exposed ureter did not show the renal abnormalities characteristic of salt-losing conditions such as adrenocortical insufficiency or salt-losing nephritis. Total renal excretion did not exceed dietary intake so that the development of sodium deficiency was unlikely. Furthermore, in some circumstances the suspect kidney was remarkably efficient at conserving sodium, clearly demonstrating that it did not continuously excrete salt entirely regardless of, physiological needs. The act of feeding was found to elicit numerous changes in renal behaviour, one of which was a sharp post-prandial fall in sodium excretion. Fig. 2 shows that the kidney with the exteriorized ureter was readily able to respond to this normal stimulus to conserve sodium.

From these observations on the sheep it is concluded that chronic unilateral ureteral fistulation, accompanied by early temporary obstruction, may disturb the ratio of sodium excretion in the two kidneys without obviously affecting other aspects of renal function.

INTERACTION OF MECHANISMS CAUSING EYE AND EYELID MOVEMENT

By Dr. D. W. KENNARD and G. L. SMYTH

Medical Psychology Laboratory, Department of Medicine, University of Cambridge

THE eyelids may be considered to be an auxiliary visual apparatus. Vision requires that the eyelids be kept open; conversely, it is interrupted when the eyelids are closed as in blinking, voluntary eye closure and closure at the onset of sleep. Also the eyelids tend to follow the vertical movements of the eyes. Thus, there are two modes of interaction between the eyes and the eyelids; one associated with closure, the other with eye 'following'.

Past work has shown that different mechanisms subserve these two functions. The mechanism of blinking described by Gordon[1] and Bjork and Kugelberg[2] consists of a brief activation of the palpebral orbicularis oculi with simultaneous inhibition of the levator palpebrae superioris. Visual following differs in that no active mechanism has been found to cause a lowering of the upper eyelid. The only muscular change detectable is a gradual decrease of levator palpebrae activity as the lid moves down.

The two functions, blinking and visual search, have been shown to be mutually inhibitory. Thus, during a demanding visual task, blinking is reduced in frequency[3,4], and, conversely, blinking occurs when the task is interrupted or ceases[5]. In the course of experiments on eyelid reaction during simple visual tasks (fixation of a spot of light), Glaser and Kennard[6] observed that blinking occurred at points of relaxation of attention.

We describe here an interaction between blinking and vertical following movements of the eyes and lids. Such an interaction has not been described previously. Movements of the visual apparatus in the vertical plane influence the frequency and form of blinking. Conversely, blinking is integrated into the normal movements of eyes and lids.

These two patterns of movement—lid closure (blinking) and vertical lid following—interact and provide interesting but complex examples of nervous integration.

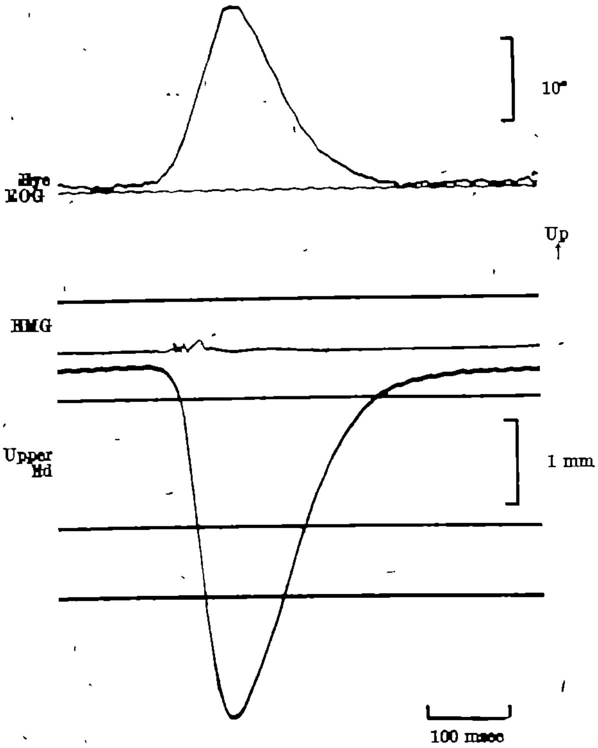

Fig. 1. A blink. The record shows simultaneous traces of the upper lid, the position of the eye determined electro-oculographically (EOG), and the electromyogram (EMG) of the upper palpebral orbicularis oculi muscle

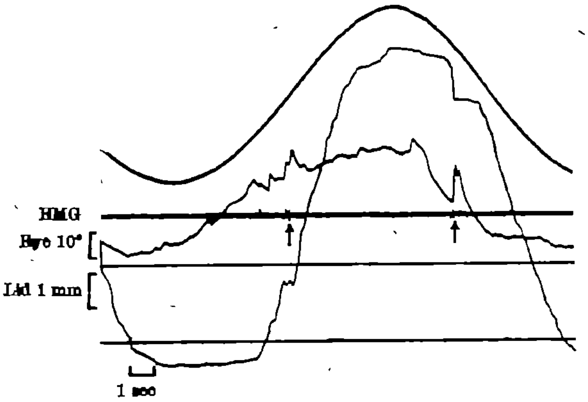

Fig. 2. Eye and upper lid movements during vertical visual tracking of a moving spot of light. Two miniature blinks occur (arrows). On the downward tracking movement the miniature blink is simultaneous with a downward lid saccade. On the upward movement a miniature blink is simultaneous with a hesitation in the lid record

The subject was required to fixate a spot of light moving in the vertical plane and following a variety of wave-forms —square step, sinusoidal and triangular. The eyelid movements were recorded with a photo-electric transducer[7] attached by means of a lever. Eye movements were recorded electro-oculographically. The electromyogram of the upper palpebral orbicularis oculi was recorded.

The simplest form of interaction observed was that between overt blinking and vertical tracking movements. Occasionally, during a demanding tracking task, blinks may not be completely inhibited, and fully formed but partial blinks occur during both the up and down movements. In common with other workers we have found the majority of blinks to be incomplete or partial, as the upper lid may stop considerably short of apposition with the lower lid. Such overt blinking may possibly be due to some source of irritation. In such circumstances evidence of facilitation is present in that the frequency of blinking is greater during downward movement than upward. We have measured such records and found the differences to be statistically significant. Sometimes simple inspection of tracking records alone suggests this fact.

However, as described here, when the visual task such as tracking is sufficiently demanding, overt blinks may be totally or very largely inhibited. Nevertheless, under such conditions evidence of blinking activity may still be present. These may be termed small or miniature blinks.

The eyelids perform the two types of movement that have been described for the eye, a smooth tracking motion, and a rapid step-like saccadic adjustment of position[6]. In executing these two types of movement the eyelids and the eye are found most often to act in unison. Thus saccades of the eye and lid occur simultaneously, though not always so. This is not the only pattern of interaction, as frequently lid saccades invoke a blink mechanism. It is understandable for this to occur during downward movement, since a downward saccade of the lid closely resembles in direction and velocity the active phase of blinking. Our records show some saccades to be associated with the typical blink movements of the eye. Thus, Fig. 1 shows that during a blink the eye moves up as the upper lid comes down. Fig. 2 shows that during downward tracking, downward lid saccades occur at the same time as upward eye rotation of 100–300 msec duration. The association with the blink is further supported by the electromyogram of the orbicularis oculi, which shows the characteristic activation of the initial phase of a blink. All grades of such blinking may be found during tracking, from the barely perceptible to the fully evolved blink.

In the course of upward tracking, such miniature blinks are also seen, but their effect on the lid is slight. They merely cause a hesitation or small notch in the record of lid movement (Fig. 3). Thus, there is mutual facilitation between the two similar functions in downward movement, although not in upward movement, and this may be considered a useful function.

Passing now to easier tasks, requiring lesser degrees of attention, a simpler pattern of interaction is found which probably represents the most elementary form of integration of these two mechanisms. Fig. 3 shows the record of the upper lid and eye obtained during upward and downward tracking of a spot of light moving slowly (3°/sec). The eye and lid follow the general motion of the target, but inspection of the record reveals superimposed minor fluctuations, which have a reciprocal relationship to each other. They can scarcely be termed blink-like or saccadic. During downward tracking, upward movements of the eye occur simultaneously with small downward lid movements. These may perhaps be considered the reverse of a blink. The record demonstrates a reciprocity between the movements of the two structures: a characteristic feature of the blink or closing action.

The central nervous mechanisms are worth discussing. The integration of the two movements probably takes

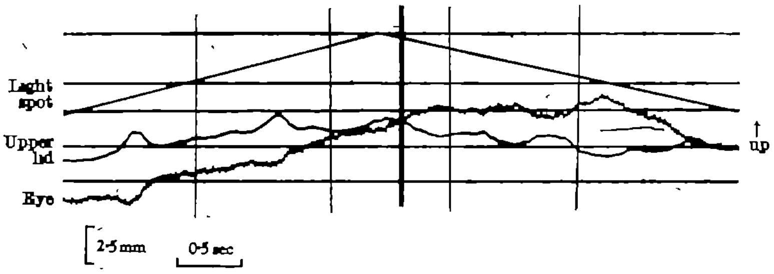

Fig. 3. Eye and upper lid movement during slow vertical visual tracking of a moving spot of light. The record shows a reciprocal relationship between the movements of the eye and lid, that is, small displacements of the lid are associated with eye displacements in the opposite direction

place at higher levels than the motor nuclei of the effector muscles, probably at the superior colliculus, which has been shown to be the nervous centre of integration of visual information and sensory data from the extra-ocular muscles. The eyelid muscles are probably to be included as extra-ocular.

We have shown that the graded mutual inhibition between the mechanisms of attention and blinking is modified by movements of the visual apparatus. Blinking is subject to phasic influence from the movements of the eyes and lids, downward movement being facilitatory and upward probably inhibitory. This interaction occurs at a centre such as the colliculus, where the neuronal fields overlap. The nervous excitatory state for blinking may be insufficient to bring about overt action, but activity of the same sign, such as downward movement, summates with it and then leads to the greater development of blinking both in amplitude and frequency. Future study of the nervous mechanisms in the responsible brain centres should provide interesting information about the performance of complex integration in the brain.

THYMUS-LYMPHATIC NODES INTERRELATIONS FOLLOWING INJECTION OF FREUND'S ADJUVANT

By Dr. GEORGE J. SVET-MOLDAVSKY and L. I. RAFFKINA

L. A. Tarasevich State Control Institute of Sera and Vaccines, Moscow, and Institute for Poliomyelitis Research, A.M.S., U.S.S.R.

UNTIL recently it has been generally accepted[1] that the thymus lacks plasma cells and antibodies. However, Ross and Korenchevsky[2] described plasma cells in the thymus of rats treated with sex hormones. Marshall and White[3] have recently reported about the formation of antibodies, plasma cells and lymphoid follicles in the thymus of guinea pigs following direct administration of antigens, and Burnet *et al.*[4] have discovered lymphoid follicles in the thymus of mice of a strain with a hereditary and auto-immunological disease.

We have observed formation of numerous plasma cells and of lymphoid follicles along with epithelial glandular structures in the thymus of albino rats treated with Freund's adjuvant.

The adjuvant, prepared as described elsewhere[5], was administered to non-inbred rats at a rate of 0·1 ml. into each of four paws and 0·2 ml. twice beneath the skin of the abdomen. 5–15 rats were killed after 2–42 days and the lymphatic nodes, the thymus and spleen examined histologically (total, 100 rats). 48 h after administration of the adjuvant in half the cases conventional accidental involution was noted, varying in degree in the thymus and lymphatic nodes as characteristic of any stress[6]. Afterwards, hyperplasia and mass production of plasma cells progressed in the lymphatic nodes, at first in the regional and then in the distant ones, as previously described[7]. During the twentieth to thirtieth days epithelioid tubercules were also formed.

The thymus likewise increased in size, and during the fifteenth to twentieth days its average weight exceeded 1·5 times that of intact rats. The correlation between the cortical and medullary substance was normal or the thymocyte-rich cortical substance somewhat predominated. In most thymuses (particularly during the thirtieth to fortieth days) typical glandular structures were noted, such as epithelial tubes or cavities lined with epithelium (Fig. 1). These were localized mostly on the surface of the cortical layer or passed throughout the cortical layer to the medullary one. Less frequently they occupied 1–2 small lobes or were located in the interlobar connective tissue. They are usually connected with epithelial strands emerging from the surface of the lobe. In the lumen of these tubes homogeneous secretion can be noted. Drops of such secretion stained intensely with pyronine were noted in the cells of the epithelium of the tube walls themselves. Close to these structures groups of mature, transitional and immature pyroninophilic plasma cells are located (Fig. 2). The plasma cells form large groups sometimes in the cortical, particularly in the medullary substance. Moreover, in the medullary substance clusters of lymphocytes can be seen in the form of follicles, sometimes with light germinal centres and transitional cell varieties. In rats the germinal centres

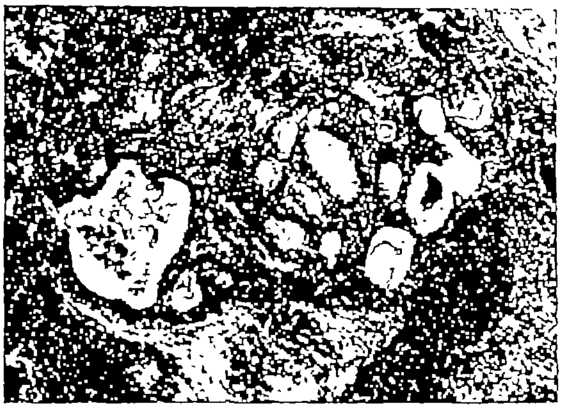

Fig. 1. Epithelial glandular structures (tubes) in the thymus of rat on the forty-second day following injection of Freund's adjuvant. (Stained with haematoxylin-eosin, × c. 52)

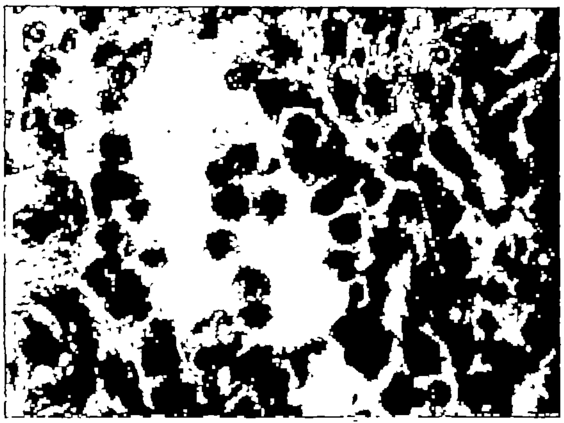

Fig. 2. Plasma cells in the rat thymus on the thirtieth day following injection of Freund's adjuvant. (Stained with pyronine-methyl green stain immersion)

are of very rare occasion, but we have observed typical germinal centres in the thymus of monkeys treated with a mixture of the brain with the adjuvant (Fig. 3). In the cortical substance of the rat thymus groups of eosinophils occur, and in the connective tissue, numerous mast cells.

In the thymuses of guinea pigs we have detected[5]; beginning with the seventh to tenth day after injection of the adjuvant, giant Hassal bodies infiltrated with polymorphonuclear leucocytes, and later on, increased development of the lymphoid cortical substance. This pattern is somewhat opposite to accidental involution.

Epithelial tubular structures have previously been found in the thymus of infantile rats[6], and in adults—during accidental involution[6], after administration of testosterone[8], fat[9], or DOCA along with accidental involution of the thymus but with hyperplasia of lymph nodes[10].

According to our results the increase of the thymus, of its lymphoid follicles, epithelial tubes and plasma cells invariably follows intensive plasma cell formation of many lymphatic nodes. A similar pattern was recorded in the thymus of pregnant non-inbred rats. In 'normal' rats with lymphatic nodes containing, if at all, but a few plasma cells no such changes were recorded in the thymus or there occurred single tubes without secretion as well as single pyroninophilic cells.

Large numbers of plasma cells in the thymus were always associated with secretion containing epithelial structures. There exists a definite functional interrelation between them. The secretion might possibly contain the hormone of cell maturation, of plasma cells in particular.

The extract of activated thymuses inhibited the development of epithelial structures in the rat thymus. Neither in intact nor in adrenalectomized rats did the extract significantly affect the production of Vi-typhoid antibodies.

In adrenalectomized rats administration of the adjuvant stimulated the appearance of plasma cells in the lymphatic nodes. Experiments on the role of adrenals in the activation of thymus are being carried out.

A quite opposite suggestion might also be made, namely, maturation of plasma cells might be attended by the formation of a substance which induces the development of epithelial structures and of the lymphoid elements of the cortex (according to the feed-back principle: lymphatic nodes–thymus). This suggestion has been tested experimentally.

It was found that the extract of lymphatic nodes abundant in plasma cells contains a substance (apparently of polynucleotide nature) which within 48–72 h stimulates in adrenalectomized rats increased reproduction of reticular cells in lymphatic nodes and the spleen and a drastic inhibition of reproduction and maturation of lymphoid and plasma cells in the lymphatic nodes and the thymus (there remain small lymphocytes-nuclei almost without cytoplasm). It will be noted that in the thymus not only do no glandular tubes appear but also its entire epithelial stroma is inhibited.

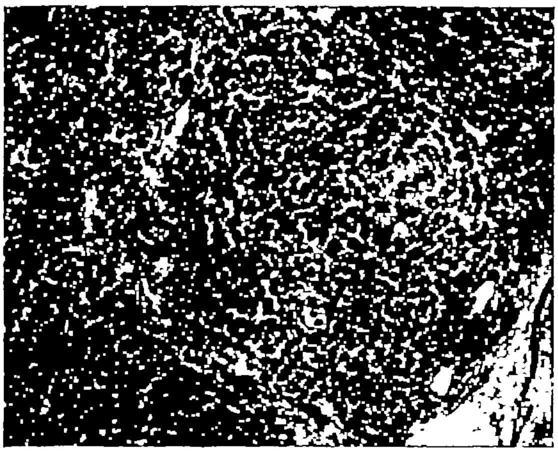

Fig. 3. Lymphoid follicles in the rhesus monkey thymus on the eighteenth day following injection of a mixture of Freund's adjuvant with the cerebral substance

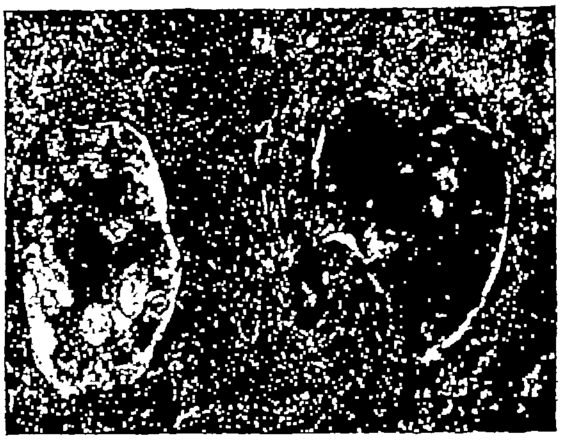

Fig. 4. Giant Hassal body infiltrated with polymorphonuclear leucocytes in the guinea pig thymus on the fifth day following injection of Freund's adjuvant

We suggest that in the thymus–lymphatic nodes system as well as in the system of all mesenchyme derivatives there undoubtedly exist manifold mutual hormonal interactions. In particular, maturation of some cells should be combined with release of substances which stimulate either directly or indirectly the reproduction of immature forms and inhibition of maturation. The study of these interrelationships is now being undertaken.

If the secretion of epithelial structures of the thymus stimulates maturation of plasma cells, mass formation of plasma cells should be associated with the formation of a substance which stimulates reproduction of reticular cells and inhibits reproduction and maturation of lymphocytes of plasma cells and the thymic epithelium.

All these tentative schemes are extremely simplified. In the light of modern evidence[11] as to the primary role of thymus in the development of immunologically competent cells and their repopulation into lymphatic nodes as well as the evidence given here, the question may be raised whether or not there might also occur a reverse repopulation of cells from lymphatic nodes into the thymus. Fontalin's experimental results[12] very likely suggest repopulation of immunologically competent cells from regional nodes into distant ones on conventional immunization.

It might be suggested that in the thymus there functions one of the general forms of information transmission from epithelial structures to the mesenchyme ones which results in the maturation of the latter.

COMPARATIVE QUANTITATIVE MORPHOLOGY OF THE MAMMALIAN LUNG: DIFFUSING AREA

By PROF. S. M. TENNEY and J. E. REMMERS

Department of Physiology, Dartmouth Medical School, Hanover, New Hampshire

THE relationship between structure and function remains a central problem for all students of Nature. Classical comparative anatomy is rich with examples of form uniquely adapted to some circumstance of life; but quantitative morphology from a comparative point of view has been only slightly exploited[1]. The lung is particularly well suited for quantitative study because from only a few elementary considerations of its function there emerge hypotheses about structure which can be tested easily.

Briefly, the lung's function is to exchange gas, and to this end it must meet certain conditions of ventilation and diffusion. Further, the volume of blood-flow through the lungs must be appropriately related, both to these conditions and to the systemic needs of the organism. In the following discussion we shall assume that cardiac output between species is roughly proportional to whole-body oxygen consumption and that the pulmonary capillaries occupy almost the entire surface area of the alveolar wall[2].

Among mammals there is a well-known relationship between body-size and metabolism[3]. The larger the animal, the greater is, in general, its total oxygen requirement; but when oxygen consumption is computed per unit of body-weight, the smaller the animal, the higher is the value.

The availability of oxygen to the organism is dependent on the quantity brought into the lungs per unit of time (ventilation) and, since oxygen is limited by diffusion, on the internal surface of the lungs. Ventilation need not be a function of the lung volume; but it is more reasonable to expect that it will be. Theoretically, it is possible to achieve any ventilation, in any sized lung, by changing the respiratory frequency, but this is most unlikely. Even moderately high frequencies are uneconomical because too large a volume is only washed in and out of the respiratory dead space. On the other hand, very low frequencies will demand a large tidal volume to achieve a given minute volume of ventilation, but in this case there is to be expected an optimal relationship between tidal volume and lung volume. If the tidal volume is too large a fraction of the lung volume, the elastic work which must be performed will be very costly, and furthermore, virtually complete replacement of lung air by fresh air with each breath will cause wide cyclic swings in the gaseous composition of alveolar air and the arterial blood. Conversely, if the tidal volume is too small a fraction of the lung volume, intrapulmonary mixing will be incomplete with each breath. Hence, some relationship between lung volume and tidal volume of ventilation is anticipated.

Intimately related to the lung volume is the consideration of its diffusing surface area. If the internal surface area of the lung is to be a function of the oxygen requirements there are two ways by which animals with different metabolic needs could achieve this relationship. When a larger diffusing surface area is called for, either the lung volume could be increased, or there could be further internal partitioning. The latter choice would indicate an increase in the number of alveoli per unit of lung volume in animals with a high metabolic rate. Therefore, the alveoli in such animals would be smaller than in those animals with a lower metabolic rate. On the other hand, if the first-named alternative were elected, small animals would require lung volumes disproportionately large for their body-size. Lung volume then would not be directly proportional to body mass but rather to body oxygen consumption, which is proportional to body-weight to the 0·74 power[4].

Except for alveolar measurements on a few species[5-8] there are only limited data with which these propositions can be examined. In the present work 26 representative mammals were examined in a search for general rules. The choice of animals included the extremes of body-size, those characterized by sluggish or vigorous locomotion; aquatic and terrestrial forms, and some that walk, swim or fly.

Metabolic data were either taken from the literature[9], or measured on resting unanaesthetized animals by standard techniques. Immediately after death the lungs were removed from the body and kept continuously inflated from a compressed-air source maintained at a constant pressure of 20 cm of water until dry fixation occurred[10]. Volume was then measured by a displacement method. Thin sections (about 100μ) of the surface of the lung were photographed under low-power magnification, enlarged prints made, and the internal surface area computed by the method of Campbell and Tomkeieff[11]. It was assumed for all species that 30 per cent of the area so measured

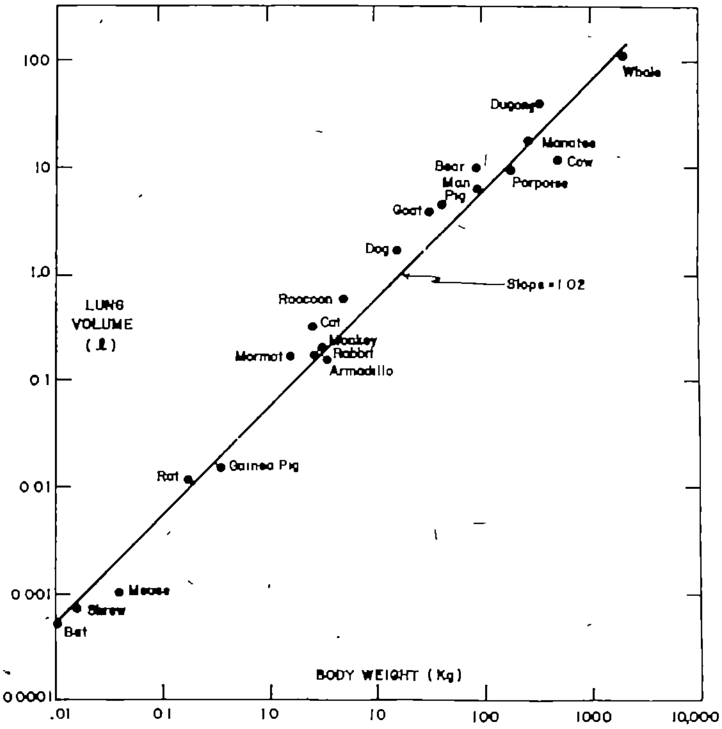

Fig. 1. Logarithmic plot of lung volume as a function of body-weight

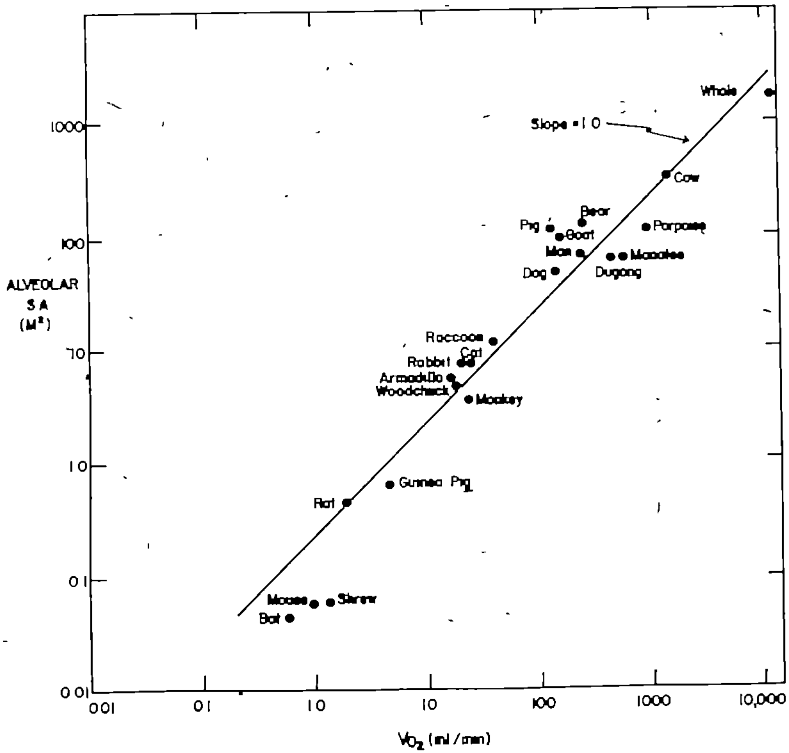

Fig. 2. Logarithmic plot of alveolar surface area a function of whole body oxygen consumption

was alveolar duct area, a fact known for certainty only in the human lung[12].

Fig. 1 illustrates the inter-specific relationship of the lung volume to body-weight. On a log–log plot the points approximate a straight line, and the slope is 1·02: Between species then the lung volume is proportional to the body-weight, and this has also been shown intraspecifically for the dog, cat and rat. Since metabolic rate correlates with body-weight to the 0·74 power it is clear that the lung volume is determined neither by metabolic rate nor body surface area, but is a constant fraction of body mass. But total ventilation is proportional to metabolic rate[4], and respiratory frequency correlates inversely with body mass to the 0·28 power[13]. Hence the tidal volume, which is the quotient of ventilation and respiratory frequency, is directly proportional to the body-weight and is thus a constant fraction of the lung volume.

The speculation about the relationship of the pulmonary diffusing surface area to the metabolic rate of the animal is confirmed to a striking degree (Fig. 2). The internal surface area of the lung correlates linearly and directly with the resting oxygen consumption over the entire range of mammalian size. A correlate of greater evolutionary significance would be maximal metabolic rate not resting; however, there is probably a proportionality between these two values[4].

It is important to note some exceptions to the general relationship between body-size and metabolic activity. The manatee, for example, has about the same body mass as the porpoise, but its metabolic rate per unit of body-weight is much smaller. The lung volumes of these animals are roughly comparable, but the lungs of the porpoise have a larger diffusing surface area. By contrast, a 170-kg manatee and an 80-kg man have about the same resting oxygen consumption and the internal surface areas of their lungs are of the same magnitude. However, the lung volume of the manatee is more than twice that of man. The mouse is larger than both the shrew and the bat, and its lung volume is proportionately larger. The resting oxygen consumption of the mouse is slightly less than the shrew and greater than the bat; and the intrapulmonary surface area is appropriately correlated.

Table 1. VARIATION OF MEAN ALVEOLAR DIAMETER WITHIN SEVERAL SPECIES. NUMBERS IN PARENTHESES REFER TO NUMBER OF ANIMALS EXAMINED. ALVEOLAR DIAMETER CITED ± 1 *S.D.*

Species	Alveolar diameter
Cat (21)	116·9 ± 14·4
Dog (8)	93·9 ± 14·1
Guinea pig (14)	65·4 ± 8·5
Mouse (6)	46·6 ± 2·4
Rat (17)	70·2 ± 6·6
Woodchuck (5)	88·3 ± 5·7

Since lung volume correlates with body-weight, but its internal (alveolar) surface area correlates with metabolic activity, then in animals with the highest metabolic rates there must be increased internal partitioning of the lungs, an arrangement which obviously demands decreasing alveolar dimensions. Table 1 indicates the intraspecific variability of alveolar dimensions in those cases where several animals were available for study. These values differ in no instance by more than two standard deviations from those of any published report[6–9], in spite of considerable differences of technique. By selecting appropriate examples from Table 1, alveolar size appears to be a function of animal size although the cat is clearly out of line. The general relationship emerges when alveolar diameter is plotted as a function of oxygen consumption reduced to unit of body-weight (Fig. 3). The slope of the best-fit regression line is 0·71 for this plot. Inspection indicates that alveolar size is not always related to body-size. The mean diameters of alveoli in whale, porpoise and man are of the same order of magnitude. Those of the racoon are larger than in the cow. The smallest alveoli are seen in the bat and the shrew, while the largest are seen in the dugong and manatee—sluggish animals of low metabolic rate but by no means the largest in the animal kingdom. The sloth lung contains the next largest alveolus. but its body-weight approximates that of a racoon. Those animals the metabolic activity of which is an exception to the body

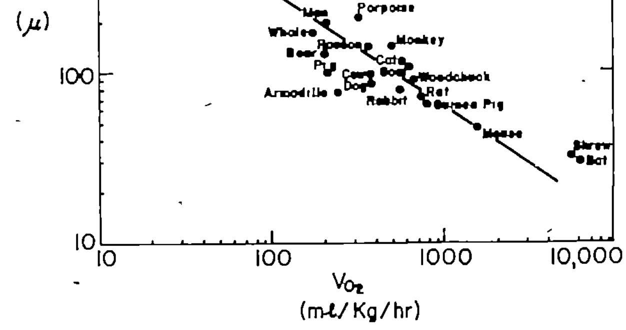

Fig. 3. Logarithmic plot of mean alveolar diameter in microns as a function of metabolic rate per unit of body-weight

surface area law remain consistent with the prediction of pulmonary diffusing surface area and alveolar size.

Summarizing, two animals of equal body-size will have lungs of the same volume, but if one has a higher rate of metabolism its alveoli will be smaller. Stated otherwise, the number of alveoli per unit of lung volume will be greater, the higher is the rate of metabolism. Or, two animals with the same oxygen consumption will have the same pulmonary diffusing surface area; but the (usually) smaller animal, with the higher rate of metabolism per unit of body-weight, will have a smaller lung and smaller alveoli. The absolute number of alveoli in the lung is clearly not a constant for all mammals, nor is alveolar volume proportional to body-weight as recently predicted[14].

The analogy between the respiratory and circulatory systems is of interest. Heart-weight is in general proportional to body-weight[4]; but capillary density in the tissues, where diffusion is important, is better related to metabolic activity[15].

Although these features are consistent with predictions based on optimal design for functional needs, the mechanism through which they are brought about is not clear. Whether or not changes can be induced in the lung's alveoli by environmental stress or whether the morphologic dimensions are fixed genetically and other functional adaptations meet changing physiological needs is a subject of considerable interest.

A BLOOD-BORNE FACTOR INFLUENCING THE ACTIVITY OF THE CENTRAL NERVOUS SYSTEM OF THE DESERT LOCUST

By DR. P. T. HASKELL and J. E. MOORHOUSE
Anti-Locust Research Centre, London

THE recent reviews by Kennedy[1,2] have outlined the data available on the differences between the gregarious and solitary phases of locusts and show that until recently little work has been done on the nervous and sensory mechanisms underlying these differences. We have sought to investigate the role of the central nervous system in this context by examining its function in relation to phase differences in reproductive ability and locomotor behaviour. This work has led one of us (P. T. H.) to formulate the hypothesis that the main difference between locust phases is to be found in the manner in which information is utilized by the central nervous system[3].

It is suggested that there is, in fact, no great difference between the sensory receptors of locusts of different phases, that in any given stimulus situation to which both solitary and gregarious locusts are exposed the same information reaches the higher centres of the nervous system and that the observable differences in behaviour between phases results from the different utilization by them of this information. It is further postulated that this utilization is dependent on the influence of a hormone balance on the integrative and other centres in the nervous system; and a corollary of this is that such a hormone balance must be itself at least partially controlled by the sensory receptors and nervous system. For example, the appropriate hormone balance relating to the maintenance of the gregarious phase must depend at least in part on the continuous, quantitatively (and perhaps qualitatively) sufficient inflow of stimuli to the nervous system of an individual locust from its fellows and/or the environment; when such inflow is reduced or terminated by a reduction in locust density, as can happen in the field and can be artificially produced in the laboratory, it may be supposed that the hormone balance changes and it is certainly true that a phase change occurs.

There is now some slight evidence of such a quantitative effect which has been discussed elsewhere[3]. But to substantiate such a hypothesis it is first necessary to demonstrate that hormones capable of influencing the operation of the central nervous system in the expected manner and direction do exist in locusts, and secondly, that interference with the hormone balance alone of a locust of a given phase produces behavioural or other manifestations associated with the opposite phase.

It has already been explained elsewhere[3] why only behavioural and reproductive criteria are utilized in the investigations reported here as phase indicators; one reason is that behavioural differences between phases are most striking, and this particularly relates to the greater locomotor activity and enhanced sensitivity to a variety of stimuli of gregarious as opposed to solitary locusts. Such differences tend to disappear or to become minimal a few days prior to moulting, and since this is a time of great hormonal activity it seemed an appropriate point at which to commence investigations. In the preliminary work described here, all of which was carried out on the desert locust, *Schistocerca gregaria*, a crude estimation of the activity of the central nervous system was made by recording the electrical activity at various points through platinum or silver/silver chloride electrodes and a conventional a.c. amplifier and counting the impulse traffic on a 'Dekatron' counter or an impulse ratemeter.

It is easy to demonstrate[4,5] that the spontaneous locomotor activity of a mid-5th instar locust is higher than that of a 5th instar hopper 12 h before moulting; on the other hand, we found that the electrical activity in the nerve cord of the former is very much less than the latter, both as regards the number of fibres firing and the frequency of the impulses, both for intact animals and for excised nerve cords. To overcome this change of electrical activity near the moult, which, from other experiments, appeared to increase progressively for a few days prior to moulting, mature male *Schistocerca* reared at high density, approximately 4 weeks after their final moult, were used as experimental animals. The insects were opened ventrally and recordings made from various points on the cord, which was not de-sheathed, while the system was irrigated with hæmolymph from locusts and with other preparations. Locusts were also dissected under Hoyle's locust saline[6] and the excised nerve cord pinned in a shallow trough in a paraffin wax block and irrigated with the various solutions; the results described here were obtained with both types of preparation.

On applying the hæmolymph taken from a 5th instar hopper approximately 12 h from the moult to the nerve cord of the experimental insect, and recording at the commissure between the first and second thoracic ganglia, after a delay of between 30 and 90 sec there was a great increase in activity due to several large fibres firing frequently (Fig. 1*A* and *B*); the same result was obtained with at least twelve different animals. Furthermore, this reaction was observed when blood from a moulting 5th instar hopper of *Locusta migratoria migratorioides* was used. On the other hand, when the nerve cord was treated with the blood of a mid-5th instar hopper there was no marked increase in activity or at most a few fibres fired spasmodically. In all cases frequent washing with locust saline restored activity to the pre-treatment-level and the experiment could then be repeated. The factors in the hæmolymph of the moulting hoppers responsible for increasing nervous activity were found to act preferentially on the brain and on all thoracic ganglia; there was some suggestion that different sets of fibres were activated by treatment of these centres. However, no increase in activity could be induced in the ventral cord by treating the sub-œsophageal ganglion.

How can the increased general activity in the nerve cord found in locusts near the moult be reconciled with their greatly reduced locomotor activity at that time? Hoyle has demonstrated[7] that the extensor tibialis muscles in the metathoracic leg of *Locusta* are mainly controlled by fast motor neurones in 3*Nv*5; if the activity in this nerve is monitored a certain level of activity is observed (Fig. 1*C*). On bathing the metathoracic ganglion with blood from a moulting hopper this activity decreases markedly (Fig. 1*D*) but can be restored to its pre-treatment level by washing the ganglion with saline. The same result was obtained when the metathoracic ganglion was isolated from the rest of the nervous system. On one occasion this inhibiting effect was noted when the supra-œsophageal ganglion was treated with moulting blood, but no results were produced by treatment of other ganglia in the cord. As a control, blood from a mid-5th instar was used to bathe the metathoracic ganglion but produced no effect. Treatment of the central nervous system of *Schistocerca* with the blood of a moulting locust therefore produces differential effects, enhanced activity in the ventral cord and depression in the motor system; it seems likely that the latter effect is a synaptic one, but whatever its origin it could explain the reduction of locomotor activity associated with the moult.

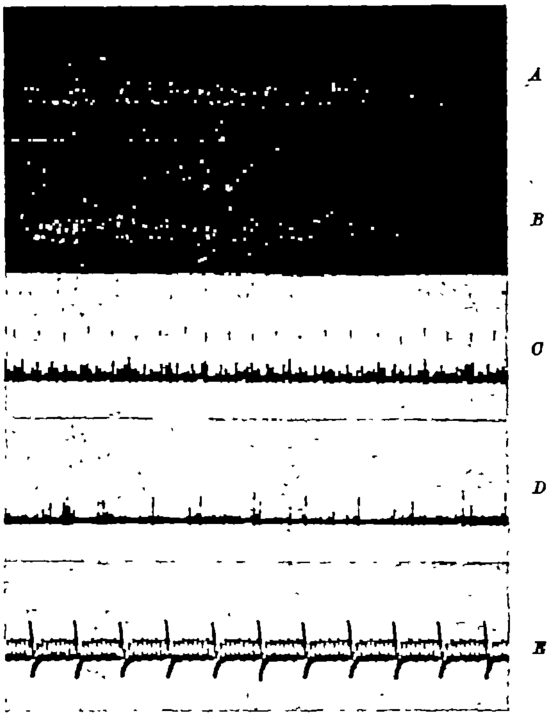

Fig. 1. Electrical activity in various nerves of adult *Schistocerca gregaria*. *A*, spontaneous activity in ventral cord between first and second thoracic ganglia; *B*, same preparation as *A*, 60 sec after treatment with hæmolymph of 5th instar hopper near the moult; *C*, spontaneous activity in 3*Nv*5 of metathoracic ganglion; *D*, same preparation as *C*, 60 sec after treatment with hæmolymph of 5th instar hopper near the moult, *E*, timing trace 1/10 and 1/100 sec

One of the processes which occurs in relation to the moulting of many insects, including locusts, is the production of the moulting hormone ecdyson by the prothoracic glands[8]. It was therefore of interest to see if this substance would bring about changes similar to those produced by blood from moulting hoppers. Accordingly, an extract from *Bombyx* pupæ, which contained a mixture of α- and β-ecdyson, was made up in locust saline in various concentrations and applied to the nerve cord in the same manner as hæmolymph. The results were identical: activity in the cord was increased while motor activity in the metathoracic motor nerve was reduced. There was some difficulty in establishing the minimum effective dose since any given solution of the hormone gave somewhat varied activity-levels, the minimum dose range being 20–100 μg of extract. Although at first sight this dose may seem high from the point of view of physiological levels, it is not unduly so since the extract used was impure and was a lepidopterous hormone; in fact, such levels are of the same order of magnitude as doses found necessary to initiate development in certain Lepidoptera[9].

These findings must be considered in relation to other observations. Carlisle[10] has pointed out that in locusts, unlike other arthropods such as Crustacea, there is no sharply defined 'inter-moult period', but that much of the time between moults may be occupied with physiological processes related to moulting. For example, in locusts, according to Malek[11], half-way through the instar a new pigmented layer has already appeared and has begun to separate from the old cuticle, and if this activity is regulated by prothoracic gland hormone it suggests a build up of concentration of the latter from mid-instar onwards. It is therefore interesting that Edney in his actograph experiments on spontaneous locomotor movement in fifth hoppers of *Locusta*[4] found that activity reached a peak half-way through the instar followed by a steep fall, and 24–36 h before the moult it had practically stopped. Hoyle[12] showed in both *Locusta* and *Schistocerca* hoppers that jumping ability declined progressively from the fourth day after moulting and attributed this to a partial neuromuscular block produced by the changes in ionic concentrations, particularly of potassium, in the hæmolymph which occur in relation to moulting; such changes would accentuate any synaptic block produced by the blood-borne factor. The effects of this factor on motor neurone activity clearly relate to the fall-off in locomotor activity in the later stages of the instar; on the other hand, the increased activity produced in the central nervous system itself may well be related to the intensification of certain physiological and growth processes also necessary at this time, when metabolism needs to be stepped up to cope with the laying down of the new cuticle and other processes involved in the moult. The volleys of impulses in the cord may, for example, be related to the intensification of respiration which normally attends a moult[13].

The foregoing suggests that in *Schistocerca* the prothoracic gland hormone is at least involved in processes which lead to differential effects on the activity of the central and motor nervous system; and the question may now be asked how this is related to phase differences. The link is provided by the finding of Carlisle and Ellis[14] that the prothoracic gland during nymphal life is larger in isolated than in crowded *Schistocerca*, and during adult life persists in the former at least until maturity, while in the latter it atrophies and disappears a few days after the final moult. This latter process is the typical course of events in adult insects since in all groups studied (except the Thysanura, which have an adult moult) the prothoracic glands degenerate after metamorphosis[8]. It is therefore to be expected that the ecdyson titre of the blood of an isolated locust would probably be higher under most circumstances than that of a crowded locust and that if it was used to irrigate a nervous system as in the experiments described here it should give similar effects to blood from a moulting insect; experiment verified this.

The evidence detailed here would constitute strong support for the hypothesis advanced earlier if it could be shown that behavioural differences existed between the phases of the desert locust which might have their origins in the neurohumoral mechanisms postulated and which could be altered in the expected direction by blood transfusion experiments. Now, although the exact significance of the reduction in motor nerve activity by the blood-borne factor is not clear, it might be expected that in isolated locusts this would have the result of reducing spontaneous activity or of raising the threshold reaction to a stimulus which could produce locomotor activity among crowded locusts. Haskell, Paskin and Moorhouse have described experiments[15] in which the locomotor reactions of hoppers of the desert locust to wind and olfactory stimuli were recorded; and Haskell and Roscow[16] have used the behaviour pattern described to determine the differences in behaviour between crowded and first, second and third generation isolated hoppers of *Schistocerca*. The results have been partially described elsewhere[3], and they confirm that isolated hoppers are less reactive or have higher thresholds than crowded hoppers when both are presented with identical stimuli. In fact, isolated hoppers for the most part could not be induced to move at all in response to stimuli which caused rapid oriented locomotor reactions in crowded hoppers; if the isolated hoppers did respond their speed of movement was lower than that of the crowded hoppers. If, however, the isolated hoppers were injected with blood from crowded hoppers then, about 24 h after the operation, they responded to stimuli to which previously they were unresponsive and also their speed of movement was increased.

Because of the time-lag before the appearance of the enhanced reactivity in these latter experiments it may be suspected that some metabolic or chemical process was involved which either removed, destroyed or stopped the production of the hormone; if it was merely that dilution of the solitary blood by the gregarious blood had reduced the concentration of the blood factor below the level at which it could inhibit activity the resultant increase in reactivity would be expected to become apparent much more quickly.

The converse experiment to that described here, that is, the injection of prothoracic gland hormone into gregarious locusts, has been carried out by our colleagues, Carlisle and Ellis (personal communication). They have injected ground-up prothoracic glands taken from crowded 5th instar hoppers of *Schistocerca* into crowded 4th instar hoppers and found that there was a significant decline in the locomotor activity of the latter which lasted for a few hours. In this case the comparatively rapid but transient effect of an increase in the prothoracic gland titre of the experimental animals argues a direct effect depending on concentration, agreeing with the experimental findings detailed here relating to the effect of ecdyson on the motor system in locusts, which can be contrasted with the slower reaction noted when solitary locusts were injected with gregaria blood.

Thus, while the evidence detailed here suggests that the hypothesis enunciated earlier in this article may be useful as a guide to the further work required, there is already in these preliminary findings a hint of the complexity which must obtain in this system.

We thank Prof. P. Karlson, of Munich, for supplying us with an extract of ecdyson.

ULTRACENTRIFUGAL CONSTITUENTS OF HUMAN AND CANINE PROSTATIC FLUID

By PROF. S. SHULMAN, P. BRONSON, M. J. GONDER and W. A. SOANES

University of Buffalo School of Medicine, V. A. Hospital and Millard Fillmore Hospital Research Institute, Buffalo, New York

THE biochemical characteristics of prostatic fluid can be described through a number of methods of investigation. For this purpose the electrophoretic patterns of human samples have been investigated, using both the filter-paper[1] and agar-gel[2] methods. As part of this programme of studies on the protein components of normal and abnormal prostatic fluid, preliminary investigations have now been made on such fluids by means of ultracentrifugal examination. Samples of human prostatic fluid were obtained by the standard urological procedure of rectal massage[3]. These were obtained both from normal individuals and those with prostatic disease. The canine samples were obtained through intravenous administration of 'Pilocarpine' to a dog in which the prostate and its urethra had been surgically isolated from the rest of the urological system. This involved the diversion of urine by connecting an isolated loop of ileum to the bladder and skin. The prostatic urethra was closed so that only uncontaminated fluid was collected on demand from the penile urethra, following the procedure described by Mason *et al.*[4].

The human sample was obtained from a 16-year-old boy (D. H.), with no evident signs of prostatic illness. The fluid was only slightly turbid and had a protein concentration of 1·12 per cent, as measured by the biuret method of Gornall *et al.*[5], using an extinction coefficient

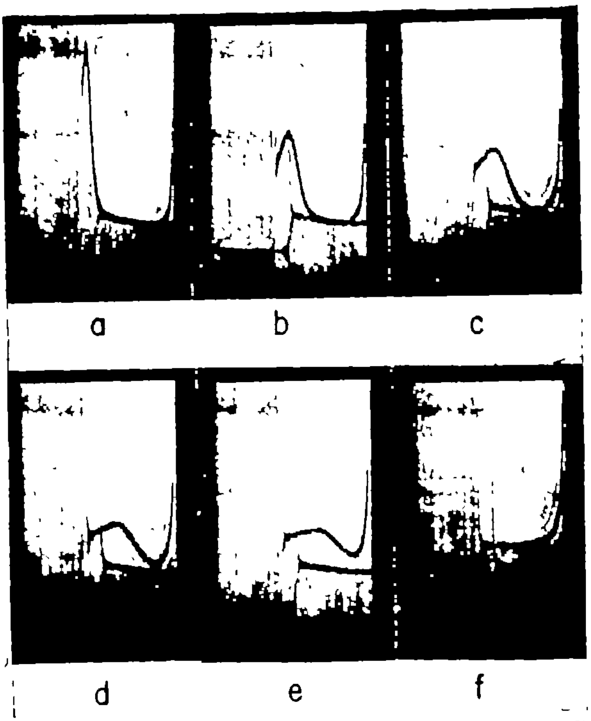

Fig. 1. Ultracentrifugal pattern of human prostatic fluid (undialysed). Concentration of protein, 1·12 per cent. Photographs at 12, 36, 60, 84, 100 and 156 min. Rotor speed, 42,000 r.p.m.

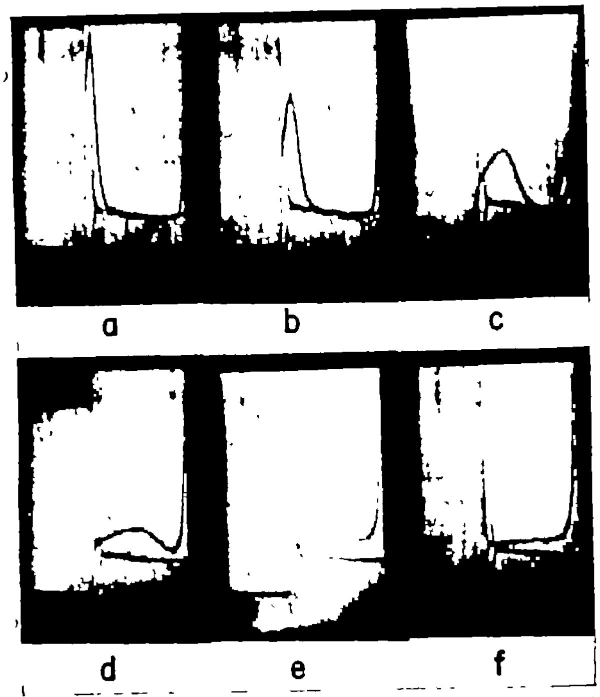

Fig. 2. Ultracentrifugal pattern of human prostatic fluid (dialysed). Concentration of protein, 0·80 per cent. Photographs at 12, 24, 60, 118, 150 and 214 min. Rotor speed, 41,200 r.p.m.

of 2·8, determined in our laboratory for pooled human serum. The volume was 0·5 ml. It was examined, without dialysis, in a first experiment in the ultracentrifuge, using a double-sector cell, with saline (0·15 M sodium chloride) in the solvent sector. Although the speed was thus limited to 42,000 r.p.m., with some consequent reduction in resolution of the components, it was felt preferable to have the advantage of the simultaneously photographed base line. In this way, even the most minor components would be clearly discernible. The schlieren patterns revealed a slowly sedimenting single boundary with a sedimentation coefficient, $s_{20,w}$, of 3·28 *S*. This value is subject to some error, since the sample had not been dialysed to provide a known solvent composition.

The pictures are illustrated in Fig. 1. There was only the slightest trace of a faster moving peak. It was not possible to measure a rate for it. After the peak had travelled far enough in the cell, one could see that a low plateau extended all the way back to the meniscus of the solution. This presumably represented a group of constituents with slower sedimentation rates. To make certain, however, that this did not actually represent some artefact resulting from the lack of dialysis preparation of the sample, a second sample of fluid was obtained from the same individual and was dialysed against 0·15 M sodium chloride. The sample, 0·7 ml., was again somewhat turbid. It was centrifuged for 10 min at 16,000 r.p.m. in a Servall refrigerated centrifuge, giving a small residue and a clear supernatant. The concentration of this sample was 0·80 per cent. In the ultracentrifuge it showed the patterns illustrated in Fig. 2. The picture is similar to that seen before, but the plateau region is somewhat less prominent. The small, faster peak is somewhat more conspicuous now, and its rate could be measured. The calculated sedimentation coefficients were 3·78 and 15·6 *S*.

Canine samples were also examined in the double-sector cell of the ultracentrifuge. The material for the first investigation was obtained intermittently for a period of 26 min. The collecting vessel was changed at various times during this procedure. It was of interest to follow the appearance and concentration of these successive samples in order to determine: (*a*) the magnitude of the initial concentration of protein in this type of prostatic fluid; (*b*) the degree to which this concentration falls as more of the sample is elicited, thus reflecting the extent of dilution of the material, as it continues to be produced (Table 1). The various samples in this group were only slightly opalescent in appearance. They were spun for 10 min at 16,000 r.p.m. in a Servall refrigerated centrifuge and gave a very slight residue. The supernatant liquids

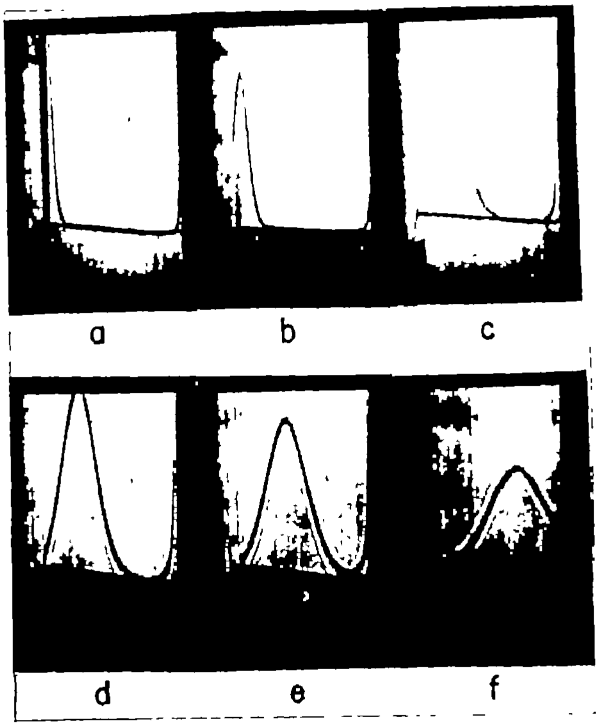

Fig. 3. Ultracentrifugal pattern of canine prostatic fluid (undialysed). Concentration of protein, 2·20 per cent. Photographs at 12, 28, 88, 120, 160 and 256 min. Rotor speed, 41,900 r.p.m.

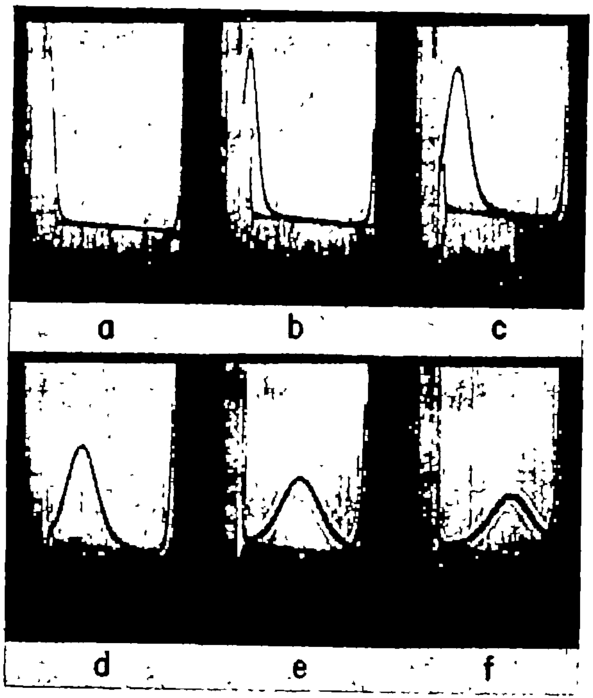

Fig. 4. Ultracentrifugal pattern of canine prostatic fluid (dialysed). Concentration of protein, 1·12 per cent. Photographs at 14, 34, 82, 156, 236 and 300 min. Rotor speed, 42,000 r.p.m.

were examined again by the biuret method and revealed no change in concentrations. Therefore, only one set of figures is given in Table 1. The first two portions of fluid were then pooled. A portion was examined directly in the ultracentrifuge, while the rest was set to dialyse against 0·15 M sodium chloride. The undialysed material was 2·20 per cent in concentration, and showed the patterns seen in Fig. 3. It is of interest to note the similarity to the human fluid. There is, however, no slow plateau region. The sedimentation coefficient was 3·12 *S*.

Table 1. Protein Concentration of Successive Samples of Canine Prostatic Fluid

Sample	Collection duration (min)	Volume (ml.)	Concentration (per cent)
1	3	3	2·94
2	3	4	1·69
3	10	10	0·40
4	10	6	0·32

The dialysed sample of canine prostatic fluid had a concentration of 1·86 per cent, and this was examined in the ultracentrifuge as such, as well as after being diluted to several lower concentrations, in order to examine the sedimentation rate as a function of concentration. The patterns showed a single sharp peak with a sedimentation coefficient in the range 2·7–2·9 *S*. Typical pictures from the examination at a level of 1·12 per cent protein are shown in Fig. 4. It is again seen that in contrast to the human material there is no slow group of components. There is also no trace of a discrete faster boundary. The sedimentation coefficients at these five different concentrations are listed in Table 2. When plotted against concentration, an extrapolated value of 2·70 *S* is obtained, with a slight positive slope. Since it is much more common to observe a negative, if not a zero, slope, it may be just as well to anticipate that experimental error conceals a zero-value slope, and thus the extrapolated figure would properly be the average value of 2·78 *S*.

Table 2. Sedimentation Coefficients of Various Concentrations of Dialysed Canine Prostatic Fluid

Ultracentrifuge run No.	Protein concentration (per cent)	$s_{20,w}$
3680	1·86	2·79
3681	1·49	2·87
3682	1·12	2·78
3683	0·74	2·71
3684	0·38	2·73

Further work is in progress to examine the ultracentrifugal patterns of pathological human fluid, as well as to obtain more precise data concerning the concentration dependence of the main component, and the content of minor constituents. Parallel investigations are being made to examine the electrophoretic patterns of these various canine and human samples. These various investigations will be reported elsewhere.

IDENTIFICATION OF AN ORGAN SPECIFIC LIPID HAPTEN IN BRAIN

By Dr. SEYMOUR JOFFE and Prof. MAURICE M. RAPPORT*
Department of Biochemistry, Albert Einstein College of Medicine, Yeshiva University
AND
Dr. LISELOTTE GRAF
Division of Experimental Pathology, Sloan-Kettering Institute for Cancer Research

THE existence of one or more organ specific lipid haptens in brain has been recognized for more than thirty years[1,2]; but little progress has been made in elucidating the chemical nature of these substances since Rudy[3,4] concluded in 1933 that the active fraction was insoluble in water, relatively stable to alkali, and phosphorus free, but not identifiable with cerebroside; Schwab[5] then showed that at least two substances must be involved since alcoholic brain extracts and an alcohol-insoluble fraction called 'protagon' reacted differently in tests with antisera to brain-lipid or brain-tissue fractions.

The criteria for brain specificity are based on the reactivity of a particular antiserum and, according to the classical definition[6], such specificity requires that: (*a*) reactions of a similar order be obtained with alcoholic extracts of brain of several different species; (*b*) that analogous extracts of a limited number of other organs be unreactive.

It is the purpose of this article to show that an anti-brain serum which satisfies the two criteria defining brain specificity reacts with pure galactocerebrosides when these are properly combined with auxiliary lipids. When compared with an established pure lipid hapten system

* American Cancer Society professor of biochemistry.

(cytolipin *H*), the degree of reactivity is such as to leave little doubt that galactocerebroside (cerasine, phrenosine) is one of the organ specific lipid haptens of brain. Since individual antisera may display unique reactivities, it is not possible to state categorically that Rudy misinterpreted the observations that led him to eliminate cerebrosides, but our results strongly suggest that his conclusion was incorrect. The chief sources of error lay primarily in the failure to appreciate the magnitude of activation (and inhibition) attributable to lipid–lipid interactions[7], and also in the immunological tests, the design of which obscured the quantitative aspects of complement-fixation measurements[8].

Because of the ready availability of galactocerebrosides in pure form and their presence in the brain of all species, the results of this study are of considerable importance for further investigations of the immunological behaviour of lipids, for the identification of other lipid haptens in brain, for the immunological study of membrane architecture, and for examination of the possible role of immunological mechanisms in various pathological conditions of the nervous system.

Rabbits were immunized by intraperitoneal injections with a particulate fraction from human or bovine brain sedimenting from a 10 per cent homogenate in 0·72 M sucrose between 800 and 20,000*g*. Injections were made three times weekly for a total of nine, each injection containing material representing 0·5 g of brain tissue. Antisera were obtained by cardiac puncture 4 days after the final injection. Individual sera were tested by complement fixation with lipid extracts of whole brain. Antibody response was variable: 3 sera from 9 rabbits were reactive. Results to be described were obtained with the most reactive antiserum. All antisera were afterwards re-tested with pure lipids.

Lipids were extracted from brain and other tissues with chloroform–methanol and then washed with water according to the method of Folch *et al.*[9]. Reactivity of these lipids with antiserum was determined by complement fixation[10] and referred to the weight of total lipid in the case of crude fractions, and to the weight of 'essential lipid' in the case of pure substances requiring the addition of auxiliary lipids. Table 1 shows that the antiserum, prepared against a particulate fraction from bovine brain, reacted to approximately the same degree with total brain lipid from ten different mammalian species. It also shows that the antiserum did not react with crude lipid extracted from bovine heart, liver, lung and kidney, and gave only a minimal reaction with lipid from spleen. Thus, this antiserum satisfies the criteria established by earlier workers for organ specificity, and the reactions of this serum recapitulate the problem of 'brain-specific lipid haptens' set forth in the literature[8].

Initial efforts to isolate the active substance sought to determine whether it would be restricted to one of the classes of lipids that can be separated by current techniques of adsorption chromatography. Accordingly, 1 g of ox brain lipid was fractionated on 100 g of alumina at 5° C using the elution solvents of Davison and Wajda[11] to give 4 fractions: I, neutral lipids, chloroform–methanol, 98 : 2 v/v (275 ml.), 225 mg; II, choline phosphatides, chloroform–methanol, 1 : 1 v/v (1,400 ml.), 250 mg; III, cerebrosides, chloroform–methanol–water, 7 : 7 : 1 (1,500 ml.), 204 mg; and IV, ethanolamine phosphatides, chloroform–ethanol–water, 2 : 5 : 2 (1,800 ml.), 230 mg. Tests for haptenic activity were performed after adding 1 part by weight of pure egg lecithin to suppress anticomplementary activity. Only fractions III and IV (cerebroside and ethanolamine phosphatide) were active. Since each of these fractions contained several components, they were subjected to chromatography on silicic acid, eluting with a continuous gradient of methanol in chloroform in a modification of the procedure described by Weiss[12]. A total of 74 mg of lipid was placed on 40 g of adsorbent in chloroform. The mixing chamber contained 325 ml. of chloroform, and the reservoir 400 ml. of methanol. Fractions of 10 ml. volume were collected, examined by thin layer chromatography on silicic acid, and recombined appropriately. Complement-fixation tests showed that activity was associated exclusively with cerebrosides. From fraction III above, 40·8 mg of cerebroside was collected in tubes 13–15, whereas fraction IV gave 3·4 mg of cerebroside in tubes 13–17.

Accordingly, pure cerebrosides were obtained from various sources and tested for their reactivity after preliminary investigation to determine the most suitable combination of auxiliary lipids. Lecithin–cholesterol mixtures of weight proportions 1 : 1 were more effective than those of either 2 : 1 or 1 : 2. With auxiliary lipid of this composition, an increase in activity of the hapten was found up to 150 parts by weight; however, the intensity of reaction (efficiency of complement binding) decreased between 100 and 150 parts by weight. The substances tested were pure cerasine and phrenosine from ox brain, a highly purified galactocerebroside from ox spinal cord, synthetic phrenosine, synthetic behenyl glucocerebroside, and a pure glucocerebroside from ox spleen. In the presence of auxiliary lipid (100 parts by weight of a mixture of equal weights of lecithin and cholesterol), galactocerebrosides all showed activity ranging from 200 to 250 units/μg whereas glucocerebrosides were unreactive at 1 μg. The antiserum was equally unreactive with cytolipin *H* (ceramide lactoside).

Isofixation curves obtained with the galactocerebroside preparations are shown in Fig. 1. The reactivities of the three natural products are indistinguishable. The synthetic phrenosine shows slightly weaker activity in the zone of excess antibody; however, two of the points in antigen excess are within the range of values obtained with the other galactocerebrosides, thus confirming the identity of the antigen in all four preparations[8]. It is probable that the small discrepancy between synthetic and natural products results from an impurity in the synthetic compound. Most of this impurity had been removed by a single recrystallization from pyridine-acetone[13]. Further evidence to support the identification of the active lipid with galactocerebroside was obtained by isolating the cerebroside fraction from the brains of five different species whose crude brain lipids were initially tested with antiserum. These fractions were recrystallized from 95 per cent ethanol, analysed, and tested. The results are shown in Table 2. All preparations were found to be free of contaminants when examined by thin layer chromatography, were found to contain galactose

Table 1. REACTIVITY OF RABBIT ANTI-BOVINE BRAIN SERUM NO. 766 (0·005 ML.) WITH ORGAN LIPIDS

Species	Organ	Units* of activity per mg of total lipid
Dog	Brain	530
Goat	Brain	560
Hamster	Brain	540
Man	Brain	600
Monkey	Brain	650
Ox	Brain	510
Pig	Brain	780
Rabbit	Brain	580
Rat	Brain	600
Sheep	Brain	770
Ox	Heart	<10
Ox	Liver	<10
Ox	Lung	<10
Ox	Kidney	<10
Ox	Spleen	20

* A unit of activity is arbitrarily defined as the quantity of lipid producing an end point of 50 per cent hæmolysis in a complement-fixation test using 6 units of complement (ref. 10).

Table 2. ACTIVITY OF RECRYSTALLIZED GALACTOCEREBROSIDE PREPARATIONS WITH ANTI-BOVINE BRAIN SERUM 766

Species of origin	Per cent hexose	Per cent N	Activity units/μg
Man	—	1·70	190
Ox	21·4	1·75	190
Pig	21·7	1·68	170
Rabbit	20·6	1·68	190
Sheep	20·8	1·74	200

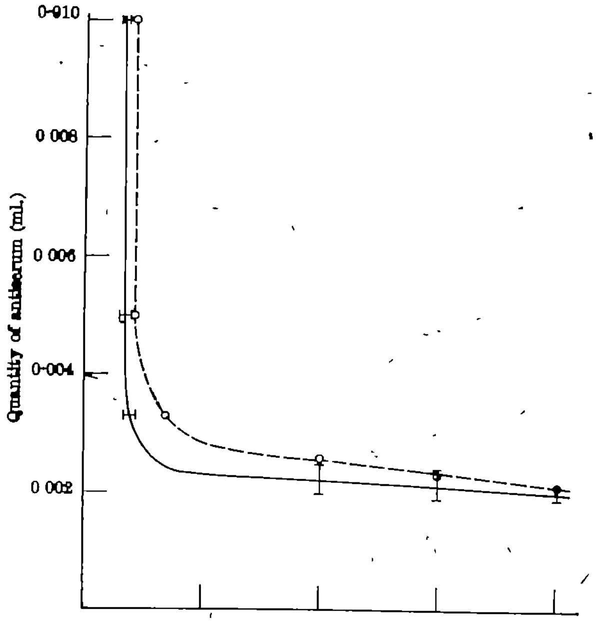

Fig. 1. Isofixation curves (ref. 10) of galactocerebrosides with antiserum to bovine brain. The solid line is drawn through points obtained by averaging the three values found with pure phrenosine and pure cerasine from ox brain, and highly purified galactocerebroside from ox spinal cord. The range of these values is shown by the short horizontal or vertical lines. The dashed line shows the values found with synthetic phrenosine

exclusively on examination of the hydrolysis products by paper chromatography, and had less than 0·1 per cent phosphorus. It is thus clear that a substance can be isolated from the brains of these species that is identifiable as galactocerebroside and reacts with exquisite sensitivity to form an immune complex with antibody prepared against brain fractions. The close correspondence of the activity of these fractions practically eliminates the possibility that the active substance is some unknown contaminant. The inactivity of glucocerebroside and cytolipin H not only attests to the specificity of the antiserum but serves as an effective control for the auxiliary lipid mixture of lecithin and cholesterol.

The knowledge that even the simplest ceramide glycoside can display haptenic function under proper conditions lends strong support to the thesis that this property is common to all glycosphingolipids[14]. Since several other substances of analogous structure are present in brain (for example, sulphatide, ganglioside), it is probable that more lipid haptens will be found in this organ. Identification of galactocerebroside as one of the brain haptens makes it possible to reinvestigate the observations of Schwab[5] in a systematic way; such investigations are in progress.

We thank Dr. David Shapiro of the Weizmann Institute for the specimens of synthetic phrenosine and behenylglucocerebroside and Dr. W. T. Norton for samples of pure phrenosine and cerasine.

REACTION OF SULPHOQUINOVOSE FROM RED-CLOVER LIPIDS WITH ANTHRONE

By R. O. WEENINK

Fats Research Laboratory, Department of Scientific and Industrial Research, Wellington, New Zealand

BY means of radiochromatography, the sulpholipid, 6-sulpho-α-D-quinovopyranosyl-(1–1′) glycerol dioleate has been shown by Benson *et al.*[1] to be present in the lipids of many green plant species. These workers measured the concentration of the intact lipid by neutron activation analysis[2]. In this laboratory a sulpholipid has been found in the acetone-insoluble fraction from red-clover (*Trifolium pratense*) leaves and, in the course of analysis, the acid hydrolysis product, sulphoquinovose, was observed to react with anthrone in a manner markedly different from simple hexoses. It is considered that the reaction of sulphoquinovose with anthrone could be developed to give a quantitative method for the determination of this sugar, and thus a quick and specific method of estimating the sulpholipid would be available. It is of interest, however, to report at this stage on the reaction of sulphoquinovose with anthrone as it could prove to be a useful means of detecting this carbohydrate in lipid hydrolysis products.

Red-clover lipids were extracted with boiling 95 per cent ethanol and the acetone-insoluble fraction was obtained as described previously[3]. This fraction (1·4 per cent phosphorus, 0·58 per cent sulphur) was chromatographed on silicic acid to obtain a further concentration of the sulpholipid. Fraction 10 (2·66 per cent phosphorus, 1·41 per cent sulphur), eluted from the column in chloroform–methanol (1 : 1 v/v) contained approximately 40

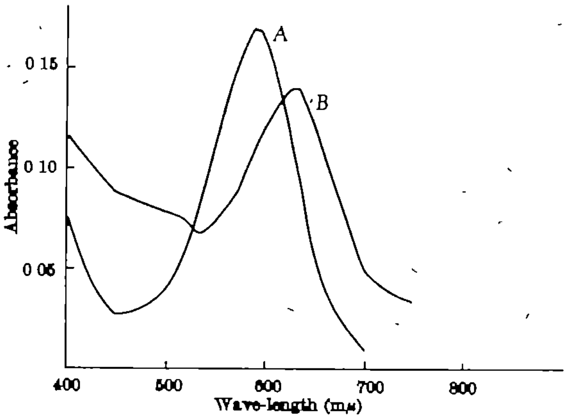

Fig. 1. Spectra of anthrone complexes. *A*, sulphoquinovose; *B*, galactose

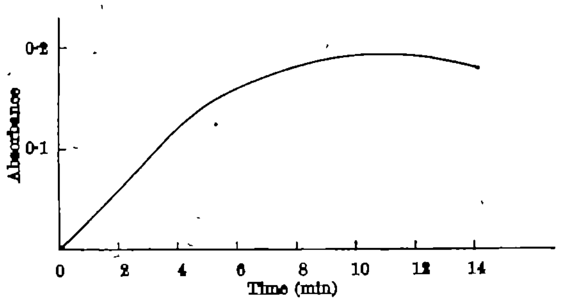

Fig. 2. Rate of colour formation of sulphoquinovose with anthrone at 100°. Conditions are those described by Bailey (ref. 5)

per cent sulpholipid. Small portions of this fraction were subjected to methanolysis[4], and the water-soluble products were acid hydrolysed for 1 h in 1·0 N hydrochloric acid at 100°. Sulphoquinovose was isolated from these hydrolysates by streaking suitable amounts along the origin of paper-chromatograms and eluting the appropriate region of the developed chromatogram (water-saturated phenol) with warm water. The eluted material was shown to be identical with synthetic sulphoquinovose by paper chromatography in six different solvent systems.

Under the conditions described by Bailey[5], the reaction of sulphoquinovose with anthrone produced a different coloured product from that normally encountered with simple hexoses. Sulphoquinovose produced an intensely blue solution with an 'Emax' at 592 mμ as against the green colours of the hexoses which have 'Emax' at 625 mμ.

A plot of optical density against wave-length is shown in Fig. 1.

Compared with galactose, the wave-length of maximum absorption has been shifted about 33 mμ towards the shorter wave-length region of the spectrum. In addition, it has been found that the heating time required to produce maximum colour formation is longer than for hexoses, 10–12 min being needed for sulphoquinovose as compared with 7 min for the simple hexoses[5]. This is illustrated in Fig. 2.

The colour intensity of the anthrone–sulphoquinovose complex has been found to change considerably even after the 30 min ageing period in the dark. In one set of experiments a solution which at 625 mμ had an extinction of 0·613 directly after ageing, increased to 0·700 in 20 min and to 0·845 after 18 h. A maximum was reached in 26 h after which time the colour gradually faded.

This behaviour of sulphoquinovose with anthrone has a parallel in hexuronic acids inasmuch as Helbert and Brown[6] have noted that these carbohydrates react in such a manner as to produce an anthrone complex with an 'Emax' at 540–550 mμ and that the colour intensity also increases on standing. These results would indicate that an abnormal anthrone reaction may result if carbon atom 6 of hexoses has acidic characteristics.

The present results indicate that the anthrone reaction could be used as a means of detecting the presence of sulphoquinovose in lipid hydrolysis products. Even in the presence of other carbohydrates it is possible to detect a small shoulder at 592 mμ thus indicating the presence of the sulphosugar. A rapid and specific chemical means of estimating the sulpholipid in plant lipid extracts would be of considerable use in this field.

I thank Dr. A. A. Benson for a gift of synthetic sulphoquinovose (barium salt) used in the chromatographic work.

RELATIONSHIP BETWEEN CROP GROWTH RATE AND LEAF AREA INDEX IN THE OIL PALM

By A. R. REES*

West African Institute for Oil Palm Research, Near Benin City, Nigeria

DONALD[1] has recently described some theoretical considerations of leaf area in relation to crop growth which are at variance with earlier published work[2,3]. He also points out that only two published accounts exist of work showing the existence of an optimum leaf area index (leaf area/ground area) for crop growth and stresses the need for more work on other crops and other environments.

Work on the growth of oil palms at the nursery stage has confirmed the presence of an optimum leaf area index with a crop very different from others studied, and in a very different environment, providing further confirmation that an optimum leaf area index is likely to be a widespread occurrence.

Donald[1] follows Davidson and Donald[4] and Iwaki[5] in postulating the existence of a ceiling leaf area index at which the net rate of growth of leaves is zero, new leaf production being balanced by the death of old leaves at the base of the canopy, and the rate of production of non-photosynthetic parts falling to zero with time.

Results from a nursery oil palm spacing experiment are shown in Fig. 1. Seedlings were transplanted at the four square-arrangement spacings of 24, 12, 9 and 7·5 in., and were gathered after 6 months growth on three sampling occasions 27 days apart. Net assimilation rates (rate of increase of dry weight per unit leaf area) were determined in the usual way, using a regression of plant dry weight on leaf area from one set of plants at one sampling to estimate the dry weight of the plants to be sampled 27 days later. This method, first used by Goodall[6], allows greater precision which is necessary with genetically heterogeneous plants. For the estimation of the relative contributions of leaf and non-photosynthetic parts to the total crop growth rate (net assimilation rate × leaf area index) the increase of photosynthetic material as a percentage of total increase for each period was obtained from the plants gathered at each sampling. No leaf weight estimates were available for the plants at the start of each period, and sufficient precision was achieved from these percentages which give results more consistent than using the mean weights from 5 plants as an indication of the population mean.

The similarity between Fig. 1 and the data of Davidson and Donald[4] (Fig. 1*b* of Donald[1]) is remarkable, virtually the only difference being that in the oil palm the photosynthetic/non-photosynthetic ratio approaches closer to unity. There is a difference in scale, however; the optimum leaf area index in the oil palm is about 3, compared with 4·5 in subterranean clover, and the ceiling leaf area index is about 5 compared with 9.

At the highest leaf area index observed, 5·2, leaf growth rate is zero. This leaf area index had been reached by the second sampling, however, and the crop growth rate for the second period occurred at the ceiling leaf area index.

---

* Present address: Glasshouse Crops Research Institute, Rustington, Littlehampton, Sussex.

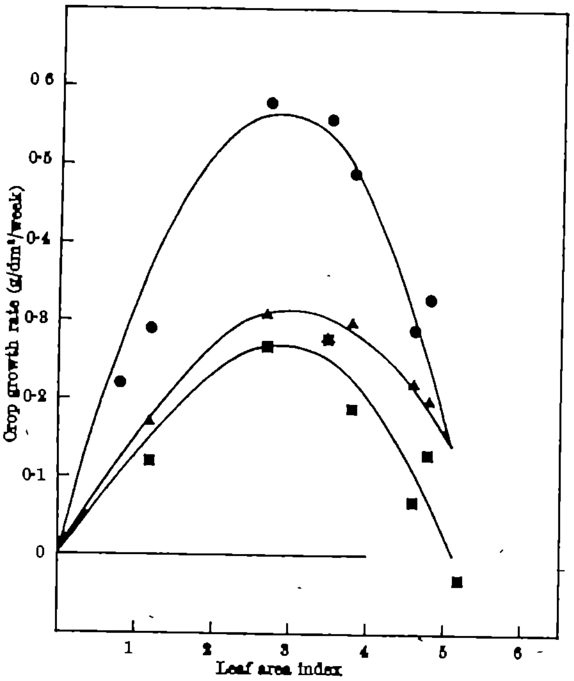

Fig. 1. Crop growth rate of nursery oil palms in relation to leaf area index ■, Leaves; ▲, non-photosynthetic parts; ●, total

The mean values for both non-photosynthetic tissues and crop growth rate for the period were just below zero (−0·02 and −0·05 g/dm^{2}/week respectively) suggesting that the fall with time shown by Fig. 1*b* of Donald[1] may be rapid, resulting in a graph similar to the curve of Davidson and Philip[2] (Fig. 1*a* of Donald[1]).

Growth analysis techniques have not been widely applied to tree crops although the work of Ovington[7] has been used by Donald[1] to demonstrate ceiling leaf area index. Somewhat similar work on plantation oil palms, Rees and Tinker[8], indicate a ceiling leaf area index of about 5 developed by the 17–20-year (age since planting in the field) stage, although the crop growth rate shows very little sign of a decline from 17 to 22 years. For a number of reasons, such as difficulties in harvesting and the availability of higher yielding material, the economic life of a plantation is not much more than 25 years, so there is little available information on older plants, although it is known that old, wild plants have a lower rate of leaf production.

The plantation is a special type of plant association where spacing is intended as the optimum for the duration of the economic life of the plantation. Although young plants have a lower respiratory load, the leaf area index is also low, and maximum crop growth rate occurs when a considerable amount of non-photosynthetic tissue has accumulated, and the leaf area index is near the ceiling value.

Accumulation of dry matter by the plants after 20–22 years occurs in the trunk material only, and a greater part of the dry-matter production is concerned with the replacement of photosynthetic tissues (apart from replacement of roots, about which very little is known, and fruit bunches). If crop growth rate is considered as the rate of increase in dry weight of the standing palms, even a 20-year-old plantation has a very low rate. There is a limit to the growth in height of wild palms; very few palms more than 80 ft. high survive, probably because the respiratory load (particularly of the trunk, which contains a high percentage of living material) increasingly tends, with age, to balance photosynthesis. The plantation palm generally has a trunk of greater diameter, so the ceiling dry matter yield would occur with palms less tall, especially as competition for light in a plantation is severe.

Determination of ceiling dry matter yield is, however, complicated because *Ganoderma* sp. attack palms, causing a trunk rot culminating in the death of the palm[9]. This fungal attack is common, particularly in palms of the height group 40 ft. and above, and in young palms, but not in the intermediate groups, and the disease is often regarded as the sole cause of death of the old palms. It is possible that the activity of the fungus is affected by the balance of photosynthesis and respiration, and that attack by the fungus is a symptom of senescence and decline in vigour.

Increasing crop production. The oil palm is similar to many other plantation crops in that establishment and early growth of seedlings (or cuttings, budwood, etc.) may be treated in a similar way to a pasture although the yield required is the maximum yield per plant not, as in a pasture, the standing crop. Here the principles described by Donald apply. For the most economic return, which is the maximum growth rate, the plants at harvesting, that is, transplanting, should be just at the optimum leaf area index. The unfavourable effects of transplanting on the palms must be minimized, especially as it has been shown that the net assimilation rate of the oil palm appears very susceptible to poor transplanting and takes a period of many weeks to recover[10]. The third consideration, important for the oil palm, is a nursery root disease, 'blast', which decimates nurseries during October–November, particularly if the plants are below a minimum size, when their susceptibility is very high.

For maximum growth rate, the optimum spacing must be worked out commensurate with increased costs of land clearance, planting costs, mulching and irrigation. With 2-ft. square planting, leaf area index reaches a value of 2·0 by early February and 3·0 a month later. Maximum growth per plant occurs at the first level and maximum crop growth at the second. For optimum plant growth, leaf area index should be about 2·0 by about mid-April, when the plants are taken to the field. For this to occur, maximum spacing should be approximately 2·8 ft. square, that is, 8 ft.^{2} land area per plant. This is very similar to recent recommendations (2·5 ft. square) by Gunn, Sly and Chapas[11].

For adult palms, problems of maximum production are more complex. The commercial yield is not the standing crop as in the case of a pasture or of a forestry plantation, and the ceiling yield concept (which applies to the standing crop) is inapplicable. The important value is the crop growth rate or annual dry matter production, part of which represents the economic yield. The commercial yield may be increased in two ways. First, the crop growth rate may be increased, and so increase the quantity of fruit without change in proportion, or, secondly, the proportion of fruit may be increased without change of crop growth rate. The latter would appear to be more promising, and is in fact what is now being achieved by selection. A decrease in stem and leaf production would allow a greater proportion of the dry matter production to be diverted to fruit bunches. The rather unexpected situation would then arise of an increase in fruit production from a decreased rate of leaf production (which would also result in a lower rate of stem formation) and focuses attention on the single growing apex of the palm as of great importance in yield determination. A study of growth rates in the apex is in progress.

PHYSICS

Multiple Flash-gap Technique for measuring Shock Wave Velocities

A NEW technique has been developed for the recording of the progress of a shock wave through a transparent material. The present communication gives a brief account of the technique and its application to the study of shock initiation of detonation in a solid explosive.

In the photographic flash-gap technique first described by Walsh[1], the arrival of a shock wave at the surface of a metal is indicated by the intense flash of light emitted from a small quantity of gas trapped in the narrow gap between the metal surface and the surface of a block of transparent material such as 'Perspex'. The light flash is thought to be caused by the rapid compression of the gas between the approaching surfaces, rapidly followed by quenching through the loss of heat to the walls, as the separation becomes small.

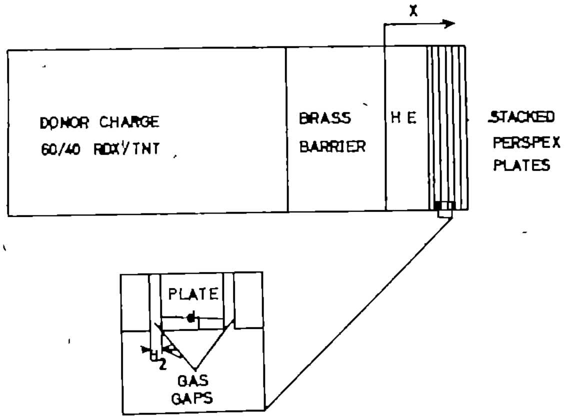

Fig. 1. Experimental arrangement. Charge diameter, 7·5 cm

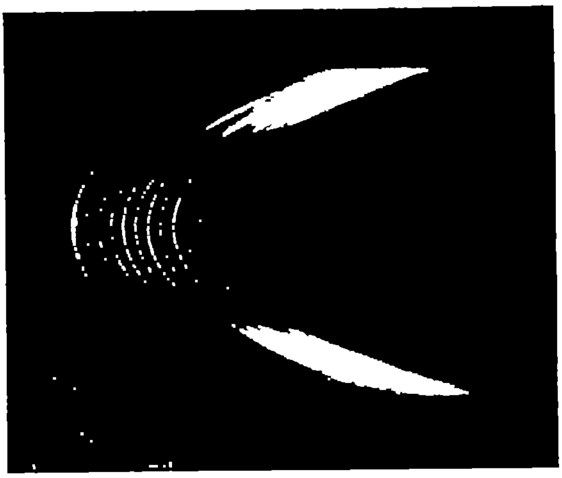
By using a stack of several 'Perspex' plates separated by narrow gas-filled gaps, we have produced a multiple flash-gap arrangement which has proved valuable in the study of accelerating or decaying shock waves. The progress of the shock wave through the stack gives a series of light flashes as consecutive gaps are closed, so that the shock wave velocity across each 'Perspex' plate can be found from a time-resolved photographic or photoelectric record of the light from the gaps.

Fig. 1 shows the multiple flash-gap arrangement used to study the accelerating shock wave in the receptor charge in a shock initiation experiment. The light flashes have been recorded by means of a 5·4 km/sec streak camera, looking through the 'Perspex' along the charge axis towards the approaching shock wave. Fig. 2 shows such a record.

In calculating the shock wave velocities from the recorded time intervals between flashes, we have assumed the time between two consecutive flashes to be composed of two parts: 1, the time for the shock wave to traverse the plate, and 2, the time needed for closing the gap. We have assumed the gap to be closed with a velocity equal to twice the particle velocity behind the shock front in the 'Perspex'. For the relation between particle velocity and shock wave velocity in 'Perspex' the data by Buchanan, James and Teague[2] have been used.



2 μsec 18 < x < 28 mm

Fig. 2. Streak camera record of light flashes produced in the experimental arrangement of Fig. 1

With plate thicknesses of 1–3 mm and gas-gaps of 0·06 mm, the time for closing the gap was from 7 per cent of the recorded time between flashes at the highest shock wave velocities measured to 26 per cent at the lowest. The uncertainty in the shock wave velocities obtained in the present experiments is about 5 per cent. Of this, 1–2 per cent is due to the time measurement. The rest is due to variations in plate thickness, which was not measured for each plate separately.

Fig. 3 shows the results of a series of 6 experiments with the charge assembly shown in Fig. 1. The thickness of explosive in the receptor charge (60/40 RDX/TNT) between the barrier and the stack of 'Perspex' plates was varied from 0 to 30 mm. The thickness necessary for transition to detonation at the charge axis, as determined in a separate series of experiments from the appearance of detonation light at the surface, was 25 mm.

Each experiment gives a record of the velocity of the shock wave as it proceeds down the 'Perspex'. As conditions behind the front determine the way in which the front velocity changes, it should be possible from such a record to find the pressure profile of the wave transmitted into the 'Perspex' if one knew the velocities of sound at different states. The front pressure of the original wave just before it reaches the first 'Perspex' plate can be

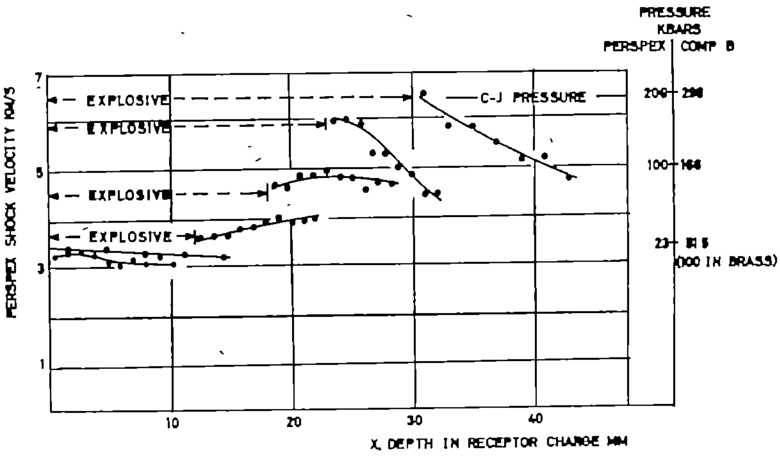


Fig. 3. 'Perspex' shock velocities versus depth in receptor charge assembly

determined directly from the record provided that shock wave data for the two materials are known. (Using two air-gaps only, Paterson and Lamb[3] have measured the Chapman–Jouget pressure in commercial explosives in a similar manner.)

In principle, one should also be able to find the whole of the original pressure profile from an analysis of the record. Even without an elaborate analysis, however, the record can often give a valuable qualitative picture of the pressure profile.

From the records in Fig. 3, one finds: first, that along the axis of the receptor charge the shock wave velocity and amplitude increase quite steadily towards detonation, and not at all so abruptly as one might be led to believe from an observation of the surface of the charge.

Secondly, the shock wave velocity in the 'Perspex' seems to increase as the wave travels into the 'Perspex' in such cases where the receptor charge has a thickness less than the expected depth of initiation. The experiments indicate that there is, in that part of the receptor charge, a region behind the shock front where the instantaneous pressure is greater behind the front than at it.

Thirdly, this region of greater pressure appears to contract and draw closer to the front as the wave moves farther into the receptor charge.

The pressures in the explosive were estimated using the Hugoniot data for detonation products of composition *B* (64/35/1 RDX/TNT/wax) given by Deal[4]. The uncertainty in this estimate is undoubtedly greater at low pressures than at pressures near the *C–J* pressure, where the chemical reaction is closer to completion.

The estimated front pressure in the experiment with the thickest receptor charge (30 mm) agrees well with the *C–J* pressure given by Deal[4].

No sign of a von Neumann spike can be observed in these records. We intend to carry out experiments with very thin 'Perspex' plates in order to look specifically for this phenomenon.

Effect of Grinding on Quartz Particles

WHETHER a vitreous or otherwise 'disturbed' layer forms on particles of quartz produced by size reduction processes has been the subject of a controversy for some time. In an earlier communication[1] we reported evidence for the absence of a vitreous or mosaic sub-surface layer. A recent paper by Sakabe *et al.*[2] leaves little doubt that, in their experiments, a thick vitreous layer was formed by the grinding procedure used. Samples were ground in a mechanical agate mortar for varying times up to 300 h and fractions of mean particle size of approximately 0·5μ were prepared by centrifuging. Some of their observations are summarized here.

(1) The initially angular particles became rounded, almost spherical, after 24-h grinding.

(2) The initial rate of solution in 10 per cent sodium hydroxide was greatly enhanced by grinding and in all cases diminished to the same steady value after about 10 h.

(3) The intensity of the (101) X-ray Bragg reflexion diminished rapidly with increasing grinding time. After 300 h of grinding the peak disappeared. Little or no broadening of the peak was observed.

(4) In the electron diffraction patterns increased grinding time resulted in a diminution in the number of spectra observed and an increase in the background intensity. No arcs or rings were observed.

We interpret these observations as indicating that the change from the quartz to the vitreous phase occurs directly without passing through a mosaic or other semi-crystalline state, as suggested by King and Nagelschmidt[3].

Samples ground under acetone in our own laboratory, either for 44 h by hand in an agate mortar or for 10 h in an agate phial using a 'Wig-L-Bug', failed to exhibit any of the foregoing phenomena suggesting the formation of vitreous material. In both cases marked broadening of the (101) X-ray reflexion was observed, but only a very slight diminution in the integrated intensity. The particles were observed to retain their angular shapes and efficient size reduction was achieved.

The difference between our results and those of Sakabe *et al.* obviously lies in the method of grinding. It is possible that in dry grinding with the high pestle pressures usual with mechanical mortars, the friction between the particles and the mortar or pestle may at times become so great that a region of the particle near the surface melts momentarily and assumes the vitreous phase on cooling.

Further investigations are necessary to determine the exact conditions under which a vitreous layer will form. From our own experiments it would seem that efficient size reduction of quartz particles can be achieved without the formation of a relatively thick vitreous sub-surface layer.

Bond Energy of Vacancies and Interstitial Atoms in Graphite

Baker and Kelly[1] have estimated that the energy to form a vacancy in graphite (that is, the energy to remove an atom from the lattice and place it on the free surface) is $U_f = 3{\cdot}3 \pm 0{\cdot}9$ eV. (The symbol ± refers to maximum limit of values.) They comment that this is less than the heat of sublimation, $U_s = 7{\cdot}5$ eV per atom, indicating an energy-relaxation of $4{\cdot}2 \pm 0{\cdot}9$ eV at the vacancy. Equality should occur[2] if the broken lattice bonds around the vacancy remain broken. In graphite, however, all the lattice bonds are unsaturated, and we would expect that the unpaired electrons of the three atoms around the vacancy would form covalent bonds with electrons derived from unsaturated bonds of adjacent atoms (cf. ref. 3). These we will call partial bonds. The net energy associated with their formation (denoted by $3U_1$ per vacancy) we identify with the required energy relaxation. Thus:

$$U_1 = 1{\cdot}4 \pm 0{\cdot}3 \text{ eV} \qquad (1)$$

An interstitial atom should likewise form partial bonds with adjacent lattice atoms, the net energy of formation of which will be denoted by $3U_2$ per interstitial. Strain energy around a vacancy or interstitial in graphite is small, and is neglected, as is also the energy associated with any electron-trapping processes. The energy, U_p, of a well-separated vacancy-interstitial pair is therefore equal to the energy to break all three lattice bonds around a lattice atom, $2U_s$, less the energy-relaxation around the vacancy and the interstitial, $3(U_1 + U_2)$. However, U_p is greater than U_f, as otherwise the surface atoms will spontaneously take up interstitial positions. From this we obtain:

$$U_1 + U_2 < 3{\cdot}9 \pm 0{\cdot}3 \text{ eV} \qquad (2)$$

We will call $U_p/3$ the effective bond energy, U_e. This represents the energy absorbed when one lattice bond between two atoms is broken and converted into two partial bonds.

The activation energy for the motion of a vacancy is $U_m = 3{\cdot}15 \pm 0{\cdot}55$ eV (ref. 1). This involves the counter-motion of a lattice atom. In its rest position this atom has two lattice bonds. We assume that at the mid-point of its jump, these are both broken (each absorbing $2U_e/3$) and each half of each bond forms a partial bond with adjacent lattice atoms, each partial bond emitting energy U_s. Thus $U_m = 4U_e/3 - 4U_s$ or:

$$U_s = 1{\cdot}71 \pm 0{\cdot}16 \text{ eV} \qquad (3)$$

The values of U_1, U_2 and U_s are probably close to each other. For present purposes we will take them to be equal and estimate their mean value U_s. Equations (1), (2) and (3) then lead to $U_s = 1{\cdot}5 \pm 0{\cdot}4$ eV. The stored energy of a vacancy-interstitial pair, U_p, is therefore $6{\cdot}0 \pm 2{\cdot}4$ eV. Half of this is to be associated with the interstitial and half with the vacancy. Experimentally the saturation value of the stored energy in graphite at reactor temperatures is about 600 cal/g (ref. 4) or 0·3 eV per lattice atom. If the damage configuration consists of single vacancies plus clustered interstitials, then the stored energy will be due principally to the bonds around the vacancies, and the saturation vacancy concentration is of order $0{\cdot}3/3{\cdot}0 = 1/10$. This is a very reasonable value[5].

We may estimate the activation energy, U_c, to evaporate interstitial clusters in graphite. The most firmly bound atoms on the edge of the cluster are attached to the edge of the cluster by two lattice bonds. U_c is thus the energy to convert these two bonds to partials (which is also the activation energy U_m for vacancy diffusion) plus the activation energy for diffusion of interstitial atoms, U_i. This latter is at least 0·4 eV (ref. 6), and is less than the 1·2 eV observed for annealing processes at higher temperatures[4], so we will put $U_i = 0{\cdot}8 \pm 0{\cdot}4$ eV.

Thus $U_C = 3{\cdot}95 \pm 0{\cdot}95$ eV. The disappearance of an interstitial cluster as the temperature is raised will thus be due first to erosion by any vacancies initially present in the lattice (U_m), followed closely by the evaporation of the interstitials remaining in the cluster (U_C). If the atoms on the edge of the cluster each evaporate in 10 sec, the value 3·95 eV corresponds to a temperature of about 1,200° C. If no vacancy clusters, dislocations or other suitable sinks are present, these interstitial atoms will condense into fresh clusters on cooling. This mechanism may contribute to the large cluster motion observed at 1,200° C (ref. 6).

The activation energy for the diffusion of a singly bonded interstitial atom along the edge of a cluster will similarly be of the order of $U_s + U_i$ or $2{\cdot}8 \pm 1{\cdot}2$ eV, which on the basis of 10^{-7} jumps per sec corresponds to a temperature of 450 ± 300° C. This implies that at the lowest power-reactor temperatures, the clusters will contain a significant number of vacant (interstitial) sites due to imperfect filling, while at sufficiently higher temperatures the atom-density in the cluster will be normal.

GEOPHYSICS

Annual Change in the Declination ('Variation') in Western Scandinavia and the North Sea

WITH reference to the letter in *Nature*[1] from Guro Gjellestad and Helge Dalseide it should be noted that the last published British Admiralty chart of declination (epoch 1960.0) does show a decrease in the annual change over the area in question, when compared with the previous chart. The isopors (lines of equal annual change) shown on the 1960 chart are given in Fig. 1 (full) together with those found for 1958 by Gjellestad and Dalseide (dotted).

Isopors appearing upon a declination chart are of necessity compiled in advance of publication of the chart, from data extending backwards and seldom fully up to date. The information deduced from these data are extrapolated values of the annual change which must be used for correcting the chart values of the declination for a period of several years subsequent to the epoch of the chart. No extrapolation formula has yet been devised to cope with the vagaries of secular change, and experience has shown that, even in the best-determined regions, extrapolation over a matter of several years is liable to errors of 1 or 2 min per year in the predicted annual change.

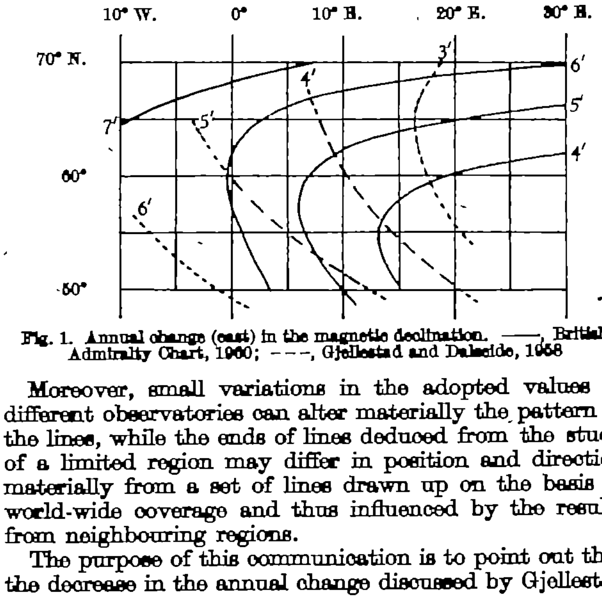

Fig. 1. Annual change (east) in the magnetic declination. ——, British Admiralty Chart, 1960; – – –, Gjellestad and Dalseide, 1958

Moreover, small variations in the adopted values at different observatories can alter materially the pattern of the lines, while the ends of lines deduced from the study of a limited region may differ in position and direction materially from a set of lines drawn up on the basis of world-wide coverage and thus influenced by the results from neighbouring regions.

The purpose of this communication is to point out that the decrease in the annual change discussed by Gjellestad and Dalseide is in fact shown in the last Admiralty world charts, and that the differences of the two sets of isopors should be treated with reserve.

[1] *Nature*, 196, 55 (1962).

WE were not referring in our communication to the last published British Admiralty chart (1960.0) which we did not know about, but to several Scandinavian charts and to other sea maps apparently using information from older charts from the Admiralty. We fully agree with Finch in his remarks. It is unfortunate that no theory of the secular variation has been developed that might be generally accepted, and that no empirical formula is known for extrapolating for the secular variation.

GEOLOGY

Geometrically Complicated Monogenetic Flow Folds

COMMON phenomena observed in gneissic terrains include the remarkable contortions shown by the compositional layers within the gneisses. Some of the more simple deformations have been analysed and accounted for adequately[1], but the more complicated contortions have been dismissed as 'flow folding', 'plastic folding', etc., with no further note.

Folded gneissic bands and enclosed mafic layers (for example, amphibolites) are often very impersistent, and show little regularity in the disposition of fold axes (crest and trough lines) and axial planes. Such folds have been considered to comprise the class of flow folds[2]. However, I have maintained that the geometrically simple folds resulting from a laminar type of plastic flow more or less perpendicular to marker layers should also be included in this class, and suggested that the more complicated flow folds in both hard rock and soft sediment result from unusual patterns of laminar flow[3]. Thus flow folds were redefined in more general terms as "contortions affecting only incompetent beds, which have thickened and thinned without the aid of ruptures above microscopic levels".

In recent years many studies have been made of superimposed fold systems[4–8], and characteristics of such systems include the development of 'hooks' in the rock distribution, and irregularities in the disposition of the fold axes and axial planes.

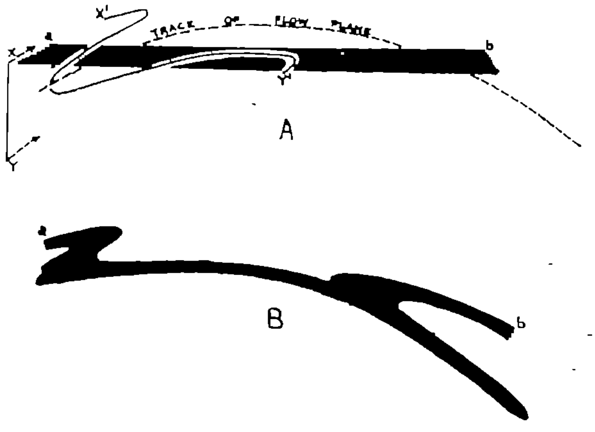

Fig. 1

In amplification of my earlier statements and to introduce a note of caution in concluding multiple folding for geometrically complicated folds, Fig. 1 shows how monogenetic folds may have peculiarities hitherto often taken to suspect the presence of superimposed folding. In Fig. 1*A* let deformation proceed by a laminar-type flow along involuted planes parallel to the broken line in the general direction of the marker layer *ab* (solid shading), so that the imaginary line *XY* is displaced to *X'Y'*. Involution of the flow planes may result from slight variations in pressures, temperatures and chemical compositions. The resulting contortion of the layer *ab* in a by-and-large isotropic plastic medium is shown in Fig. 1*B*, where 'hooks' and folds facing opposite directions have been developed.

Recrystallization of Zircon as an Indication of Contact Metamorphism

ZIRCON ($ZrSiO_4$) is generally regarded as the most refractory accessory mineral present in the common rock types[1]. According to Poldervaart[2], incipient granulation and recrystallization of zircon when exposed to ultrametamorphic processes can be expected only in a stage as high as the sillimanite grade. Investigations in quartzite xenoliths in the southern norite belt of the Bushveld Igneous Complex of the Transvaal (South Africa), however, indicate definitely that these processes can be caused by usual contact metamorphism and that the foregoing conceptions should be revised.

A zircon concentrate from a thermally reconstituted quartzite slab floating in the Bushveld norite north-west of Pretoria shows a characteristic preponderance of recrystallized zircons, that is, crystals displaying a rounded or fractured core enveloped in a mostly idiomorphic, transparent shell (Fig. 1). Statistical evaluation of the material revealed that from 300 grains counted 137 (45·66 per cent) show clear signs of recrystallization. In a number of others the core is not so easily recognizable, but appears as a cloudy spot, surrounded by a somewhat 'ghostly' outline. A comparison of these metamorphosed quartzites with the 'normal' quartzites of the Pretoria series outside the Bushveld aureole shows that the latter contain scarcely any zircons displaying recrystallization phenomena (< 2 per cent).

The results thus obtained are not difficult to explain. It is self-evident that the rounded or fractured kernels of the recrystallized zircons represent minute zircon 'pebbles' in all stages of attrition, originally representing the bulk of the heavy mineral fraction of a sedimentary rock. Accordingly, these zircons did not originate in this rock; they were merely deposited after having undergone transport, during which they developed their characteristic pebblish or fragmental shape (cf. Fig. 1). Speaking in genetic terms, they cannot be referred to as primary constituents of the rock formed here *in situ*, but only as secondary or allogenic components derived from outside sources and dumped together with other sedimentary detritus finally constituting an arenaceous rock.

Their host-rock later being subjected to contact metamorphism, these zircons suffered thermal recrystallization, that is, a stage of secondary growth resulting in the development of an outer shell which is mostly water-clear and idiomorphic, showing often a model-shaped crystal form with sharply pointed pyramidal terminations (Fig. 1). In contrast to the parent detrital grains, these outgrowths were formed in place; hence they are primary or authigenic constituents of the rock. The cores enclosed

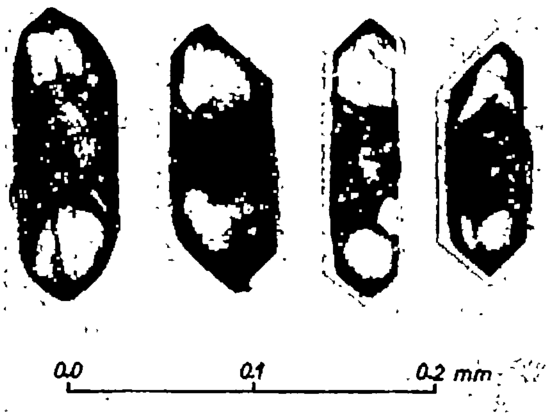

Fig. 1 Recrystallized zircons from a metamorphosed quartzite in the Bushveld norite north of Vissershoek (north-west of Pretoria)

in these shells now represent sedimentary relict structures betraying the original sedimentary character of the reconstituted rocks.

As particularly emphasized by Poldervaart[2], elongation frequency curves usually yield valuable criteria for a quantitative description of a given zircon concentrate. It may be noted, therefore, that the elongation frequency curve of the zircons from the metamorphosed quartzite shows two maxima separated by a somewhat irregular gap (Fig. 2A), being proof that this crop is 'bigenetic', containing a sedimentary fraction with a length/breadth maximum at 1·5 and a metamorphic one with a length/breadth maximum at 2·0. It seems noteworthy that curves displaying this general set-up were already inferred from theoretical considerations by Poldervaart[2], although in connexion with magmatic rock types. Zircons from the common quartzites of the Pretoria series show the usual elongation frequency distribution characteristic of well-sorted sediments with only one distinct maximum (Fig. 2B).

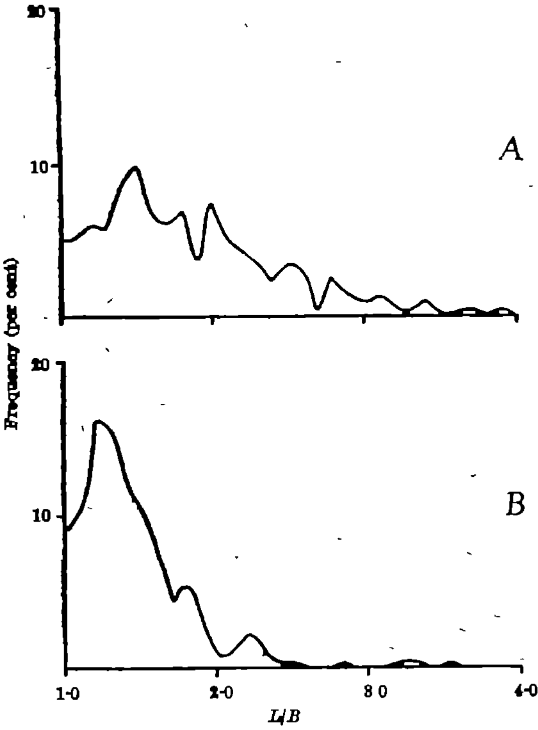

Fig. 2. Elongation (*L*/*B*) frequency curves of: *A*, zircon crop from reconstituted quartzite, as mentioned in Fig. 1; *B*, zircon crop from usual quartzite of the Pretoria series (Magaliesberg quartzite, Silkaatsnek)

Although it seems to be established from these findings that the refractory properties usually ascribed to zircon with regard to recrystallization are less significant than conceived by previous investigators, there can be no doubt about it that this mineral is actually capable of surviving metamorphic processes as a solid body, forming relict structures in newly developed crystals. As has been pointed out convincingly by Poldervaart and Eckelmann[3] and Hoppe[4], these relict bodies are still preserved in zircons of completely reconstituted 'ultra-metamorphic' rocks of sedimentary derivation. Accordingly, the new observations as recorded in this communication in no way restrict or even invalidate the petrogenetic significance of morphological zircon studies. It seems to be of particular interest, therefore, to apply the zircon method in connexion with a transformistic conception of the Bushveld norites advanced by S. van Biljon[5], explaining these magmatic rocks as transformation products of the upper part of the Pretoria series and the afore-mentioned quartzite xenoliths as 'undigested' relics of the latter.

ASTRONOMY

Determination of Relative Ages of Lunar Craters by Albedo and Polarization Measurements

One of the most important tasks in selenology is to establish the relative ages of different parts of the lunar crust. It may be argued that, during the lifetime of a crater, its floor would be darkened at a uniform rate by the destructive effects of ultra-violet light on the rock crystals. The empirical relationship:

$$2 \log \rho + \log \Delta = 0 \qquad (1)$$

may be fitted to the albedo (ρ) measurements of Markov and Fedorets[1], where Δ is the diameter of a crater in kilometres.

Solid materials polarize less light if they are fragmented, but there comes a point when the degree of pulverization is such that the polarization again increases due to the change in the scattering properties of the material. On the Moon, there is a natural agency for breaking down the rocks in the form of meteorite collisions. The degree of roughness will vary from one region to another, and this may be expected to bear some relationship to the age of the rocks in that region. A freshly formed impact crater will have some covering of rock dust, and a young igneous crater will probably have a covering of volcanic ash. In either case, the microstructure of the floor will be comparatively smooth. As time elapses, the roughness of the floor of a crater may be expected to pass through a maximum, since the fragmentation process will yield large rock blocks at first and these themselves will be subject to gradual pulverization. Hence the maximum proportion $P_{\max}$ of light polarized by an average region should pass through a minimum. Measurement of $P_{\max}$ of a given region would thus yield two possible ages. Dzhapiashvili's[1] measurements of $P_{\max}$ may be used to show that this is the case, and that ($P_{\max}$ expressed as a percentage):

$$3 \log (P_{\max} - 7) = 4 \log (\Delta \sim 170) - 6 \qquad (2)$$

Because of intrinsic differences between the albedo of rocks at different points of the Moon and because the initial degree of roughness will certainly differ from point to point, equations (1) and (2) are essentially statistical. Improved relationships may be obtained as a greater quantity of fundamental data become available, for only then will the number of measurements be sufficient to warrant segregating the points according to whether they lie in the dark maria or in the brighter continental regions. However, interpreted broadly, both relationships point to the fact that the larger lunar craters are the older. In particular, on the theory outlined here, the rocks of the maria would have to be the oldest on the Moon. Yet, considerations of the relative frequency of occurrence of continental and post-mare craters indicate that the continents are some six times older than the maria. This difficulty may be resolved if the continents and maria differ in chemical composition.

CRYSTALLOGRAPHY

Refinement of the Crystal Structure of Antlerite

THE crystal structure of antlerite, $Cu_3(SO_4)(OH)_4$, was determined by Araki[1] while J. J. Finney was also working on the structure. This refinement represents the final results of the two independent determinations.

A specimen of antlerite from Chuquicamata, Chile, was used for the refinement. Data from nine reciprocal levels, zero, one and two for each of the a, b and c axes, were collected by means of multiple film pack Weissenberg photographs. Molybdenum $K\alpha$-radiation was used throughout the investigation. Of a possible 991 unique reflexions, 723 were observed. Intensities were obtained by visual comparison with a known scale.

Antlerite is orthorhombic, space group *Pnma*. The cell dimensions, $a_0 = 8·226$, $b_0 = 6·046$, $c_0 = 11·978$ Å, determined from precession photographs agree with those determined by Araki. The cell formula is $Cu_{12}(SO_4)_4(OH)_{16}$.

Refinement of the antlerite structure was effected by the method of least squares. Parameters obtained by the senior author's structure determination were used as input for the refinement and the final parameters are listed in Table 1.

Table 1. PARAMETERS OBTAINED BY LEAST SQUARES REFINEMENT

	Cu_1	Cu_2	S	O_1	O_2	O_3	OH_1	OH_2	OH_3
x	0·0052	0·2897	0·1304	0·262	0·195	0·033	0·285	0·701	0·046
y	0·2500	0·0022	0·2500	0·250	0·250	0·047	0·250	0·250	0·503
z	0·0015	0·1259	0·3641	0·283	0·476	0·348	0·026	0·779	0·102
B	0·65	0·65	0·49	0·80	1·00	1·17	0·58	1·39	0·90

Table 2. RESIDUALS OF THE ANTLERITE REFINEMENT

Level	Reflexions	R
$0kl$	65	0·092
$1kl$	75	0·107
$2kl$	55	0·099
$hk0$	54	0·120
hk1	54	0·086
$hk2$	38	0·107
$h0l$	194	0·089
$h1l$	50	0·124
$h2l$	138	0·087
Total observed	723	0·096
Unobserved	268	
Total	991	

For the refinement, the entire matrix was computed and inverted. Twenty-one positional parameters, nine temperature factors and nine scale factors were allowed to vary. Only isotropic thermal parameters were used. The residuals for each reciprocal level are given in Table 2. The correlation matrix was calculated for the last cycle, but no large interactions between parameters were observed.

There are two crystallographically distinct copper atoms in the structure each of which has a somewhat distorted octahedral co-ordination. Cu_1 has four hydroxyl groups (OH_3) nearly coplanar at distances of 1·97 Å and one hydroxyl (OH_1) and one oxygen atom (O_2) at 2·32 and 2·56 Å respectively. Cu_2 has three hydroxyl groups (OH_1, OH_2, OH_3) and one oxygen atom (O_3) also nearly coplanar at distances of 1·91, 1·91, 2·02 and 2·05 Å respectively and two oxygen atoms (O_1, O_2) at distances of 2·37 and 2·41 Å. Co-ordination about the sulphur atom is four-fold with the average bond-length being S—O = 1·46 Å. The average bond-angle O—S—O = 109·5°. Bond-lengths are considered accurate to ± 0·02 Å.

The structure consists of systems of connected Cu_1 and Cu_2 polyhedra extending parallel to b-axis. The Cu_1 and Cu_2 polyhedra are linked to each other by one OH_3 group and also by OH_1 and O_2. However, one system is linked to another by only two weaker bonds, Cu_2—O_1 (2·41 Å), in the c-direction. This accounts for the perfect cleavage parallel to (001).

We thank Dr. A. Rosenzweig of the University of New Mexico, Albuquerque, New Mexico, for supplying the sample of antlerite, and Dr. S. W. Bailey, of the University of Wisconsin, Madison, Wisconsin, for use of the X-ray equipment. Computations were carried out on the *CDC* 1604 computer at the University of Wisconsin Numerical Analysis Laboratory.

Determination of Space-Groups using Anomalous Dispersion

IN the usual method of determining space-groups, the presence of face or body centring and of screw axes and glide planes is detected by examining the systematic absences of reflexions. However, it is not possible to establish by such a procedure the presence or absence of a centre of inversion, a rotation axis or a mirror plane. This is because the translation-free symmetry elements do not lead to any characteristic absences for the reflexions; also, the symmetry of the X-ray diffraction pattern of a crystal is not exactly the same as that of the point group of the crystal itself, but only the corresponding Laue group which has an additional centre of inversion added to it.

In order to test whether the crystal is centrosymmetric or not, statistical methods have geen developed by Wilson *et al.*[1–4] and by Ramachandran and Srinivasan[5]. However, considerable doubts have been expressed about their practical applicability as distributions having properties in between the two limits have often been encountered, and the distributions are also affected by the presence of (a small number of) heavy atoms. It would therefore be worth while examining a more straightforward method of testing the presence or absence of centrosymmetry. This seems to be possible making use of anomalous dispersion.

When anomalous dispersion effects are taken into account, it is found that the symmetry of the X-ray diffraction pattern of a crystal is exactly the same as that of the point group symmetry of the crystal itself. Also, the translation-free symmetry elements, such as a centre of inversion, a rotation axis or a mirror plane, lead to the Bijvoet difference $\Delta I (= I_H - I_{\bar{H}}$, where I_H and $I_{\bar{H}}$ are the intensities of the direct and inverse reflexions including anomalous dispersion effects) being systematically zero along certain rows and planes in the reciprocal lattice. Thus, $\Delta I = 0$ for all reflexions for a centrosymmetric crystal. Similarly, $\Delta I = 0$ for all $0k0$ reflexions if a mirror plane is perpendicular to the b axis and for all $h0l$ reflexions if a 2-fold axis is parallel to the b axis. The systematic absences of the Bijvoet difference have been worked out for all the point groups, and it is found that an examination of these extinctions can reveal the presence or absence of the translation-free symmetry elements in a crystal.

Thus, the systematic extinctions of the Bijvoet difference can give uniquely the point group of a crystal. On the other hand, the usual systematic absences give the elements of the space-group which involve translational symmetry. Combining these two types of information, it is possible to write down a diffraction symbol for all the 230 space-groups, similar to that adopted by Buerger[6], except that the new symbols will contain the point group of the crystal, the lattice type and the translational elements of the space-group which are present[7]. It is found that all the space-groups except $I222$, $I2_12_12_1$ and $I23$, $I2_13$ can be uniquely determined excluding, of course, the enantiomorphous pairs.

However, even the enantiomorphous pairs can be identified in a certain sense. Although it would not be possible to say from the symmetry of the Bijvoet difference whether the space-group is one or the other (say $P4_1$ or $P4_3$), the two crystals which are enantiomorphous to each other can be distinguished by examining the Bijvoet differences. In this sense, it may be said that the method discussed here can differentiate also between the enantiomorphous space groups.

CHEMISTRY

Thin-Layer Graphited Carbon Black as the Stationary Phase for Capillary Columns in Gas Chromatography

GOLAY pointed out in his early papers[1,2] that excellent capillary columns could be produced by replacing the smooth inner wall area of a tubular column by a uniform porous layer of the support material. Petitjean *et al.*[3] and Mohnke *et al.*[4] were the first to use adsorption-type tubular columns. Both of them invented special methods for preparing alumina and silica adsorption layers from the materials of the walls by chemical reactions. The following general method can presumably be used for depositing any solid substance on the walls of open tubular columns. Here we report our results using carbon black graphited at 3,000° C (surface area $72 \cdot 8$ m^2/g)[5]. 15 g of this carbon black was suspended by rapid stirring in a mixture of 220 ml. trifluortrichlor-ethane and 30 ml. carbon tetrachloride. The carefully cleaned copper tube (in Fig. 2 silvered copper) was filled with this suspension. One end of the tube was closed and the open end was fed cautiously and slowly in a special oven to evaporate the liquid. After this procedure the carbon black remains on the wall of the column in the form of an adherent porous thin layer.

The gas chromatographic apparatus was similar to that already described. A flame ionization detector was used with a fast recorder (full scale time 0·3 sec). The carrier gas was hydrogen, the sample size (syringe) was always 0·2 µl. The columns are identified by the original inner diameter of the metal tube and with the weight of carbon black covering the wall per metre of column-length.

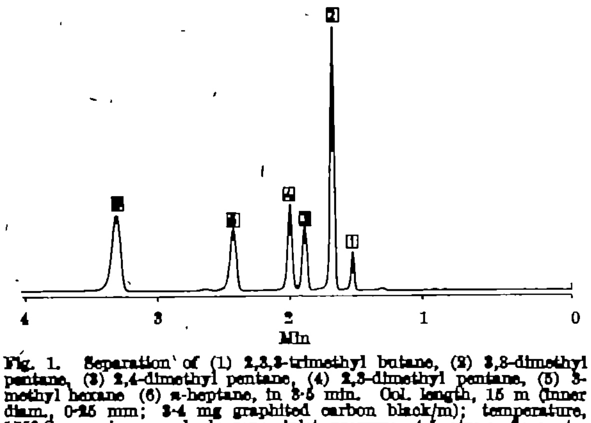

Fig. 1. Separation of (1) 2,2,3-trimethyl butane, (2) 3,3-dimethyl pentane, (3) 2,4-dimethyl pentane, (4) 2,3-dimethyl pentane, (5) 3-methyl hexane (6) *n*-heptane, in 3·5 min. Col. length, 15 m (inner diam., 0·25 mm; 3·4 mg graphited carbon black/m); temperature, 175° C; carrier gas, hydrogen; inlet pressure, 4·5 atm.; flow-rate, 3·2 ml./min (room temperature); sample size, 0·2 µl.; bypass ratio 1 : 1,070. Flame ionization detector with electrometer amplifier and quick recorder

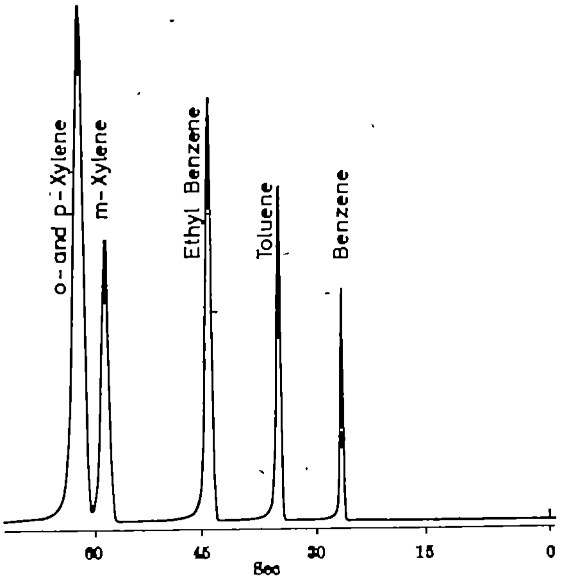

Fig. 2. Separation of (1) benzene, (2) toluene, (3) ethyl benzene, (4) *m*-xylene, (5) *o*- and *p*-xylene in 70 sec. Col. length, 15 m (silvered copper; inner diam., 0·25 mm; 5·4 mg graphited carbon black/m), temperature, 245° C; carrier gas, hydrogen; inlet pressure, 2·7 atm.; flow rate, 2 ml./min (room temperature); sample size, 0·2 µl.; bypass ratio 1 : 1,050. Flame ionization detector with electrometer amplifier and quick recorder

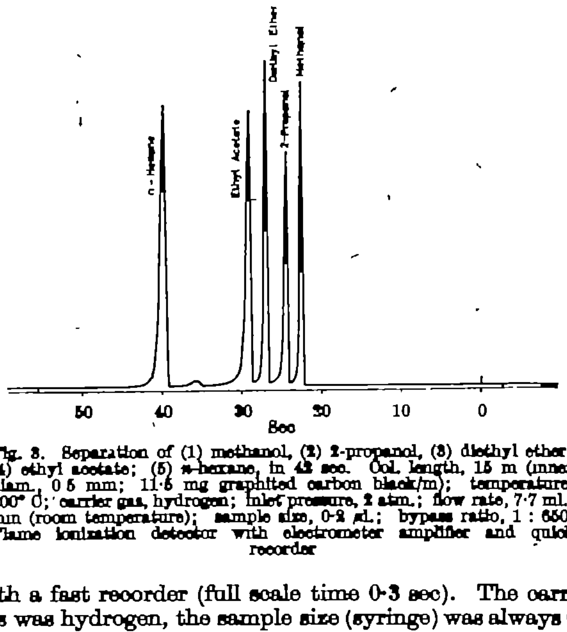

Fig. 3. Separation of (1) methanol, (2) 2-propanol, (3) diethyl ether; (4) ethyl acetate; (5) *n*-hexane, in 42 sec. Col. length, 15 m (inner diam., 0·5 mm; 11·5 mg graphited carbon black/m); temperature, 200° C; carrier gas, hydrogen; inlet pressure, 2 atm.; flow rate, 7·7 ml./min (room temperature); sample size, 0·2 µl.; bypass ratio, 1 : 650. Flame ionization detector with electrometer amplifier and quick recorder

Fig. 1 shows a relatively slow analysis of six heptane isomers available in our laboratory, run at a column temperature of 175° C with a 15 m column (inner diam. 0·25 mm and 3·4 mg carbon black/m). With a similar 30-m column we have made routine analyses of C_1–C_7 paraffins for three months without any change in retention times.

The quick and unusual separation of the xylene isomers is illustrated in Fig. 2. *m*-xylene and *p*-xylene are perfectly resolved in 70 sec with a 15 m column (inner diam. 0·25 mm and 5·4 mg carbon black/m) at 245° C, while the *o*-xylene and *p*-xylene remain unresolved.

In Fig. 3 the separation of four oxygenated compounds is shown in 42 sec at 200° C on a 15-m column (inner diam. 0·5 mm and 11·5 mg carbon black/m). Tailing is relatively small. The retention times of the oxygenated compounds, relative to those of hydrocarbons, are remarkably short.

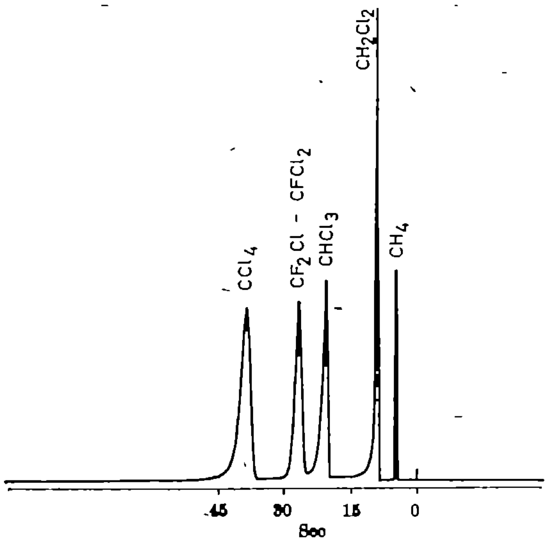

Fig. 4. Separation of (1) methane, (2) dichlor-methane, (3) trichlor-methane, (4) CF$_2$Cl—CFCl$_2$, (5) tetrachlor-methane, in 45 sec. Col. length, 8 m (inner diam., 0·5 mm; 12·8 mg graphited carbon black/m); temperature, 80° C; carrier gas, hydrogen; inlet pressure, 3·8 atm.; flow rate, 35 ml./min (room temperature); sample size, 0·2 µl.; by-pass ratio, 1 : 200. Flame ionization detector with electrometer amplifier and quick recorder

In Fig. 4 the analysis of four chlorinated paraffins in 45 sec at 80° C is shown on an 8-m column (inner diam. 0·5 mm and 12·8 mg carbon black/m). The flow rate of the carrier gas was 35 ml./min, extraordinarily high for capillary columns. We carried out rapid quantitative analyses of halogenated paraffins on similar columns with relative errors less than ± 2 per cent.

The quantity of sample actually reaching the column was $0{\cdot}12 - 0{\cdot}15 \times 10^{-4}$ g in Figs. 1–3 and $1{\cdot}4 \times 10^{-4}$ in the last chromatogram.

We used the same method with some success in preparing thin layers of alumina and silicon carbide on capillary columns for the quick separation of low-boiling hydrocarbons.

We thank Prof. U. Hoffmann and H. P. Boehm for discussions and for providing samples of graphited carbon black.

A Reliable System for the Introduction of Samples to Gas Chromatographic Columns, particularly suited for Quantitative Capillary Column Analysis

During the past few years a number of different injection systems have been used with capillary columns, but these have either been restricted to favourable samples or have given quantitative results of doubtful validity. The system described here enables the composition of any sample to be evaluated quantitatively.

If a sample of convenient size is placed in a vessel containing a suitable involatile solvent through which an inert gas is continually passed, then the concentrations of the various components will decay exponentially with time and at rates determined by their partition coefficients with respect to the involatile solvent.

A small sample of the exit gas from the vessel can be easily admitted to a capillary column by means of a gas sampling valve. If the gas sample is taken shortly after the admission of the bulk sample to the dilution system then the chromatogram which is obtained is relatively richer in the components of lower partition coefficients than was the original bulk sample. Samples of gas taken later will show progressive reduction in the ratio of low to high partition coefficient components.

If the whole of the original bulk sample could be chromatographed as a series of small samples from the dilution system, each small sample being of a size commensurate with the column requirements, then, although no single chromatogram would represent the original mixture, the sum of all the chromatograms would give the peak ratio which would have been obtained from the chromatogram of the original mixture.

In practice, it is unnecessary to take an infinite number of samples, providing the detector used has a linear response and providing the solvent used in the dilution system is the same as that used for the column stationary phase and is at the same temperature. In this case two samplings will suffice and the following equation may be applied to calculate the mass ratio of any pair of components:

$$\frac{M_1}{M_2} = \frac{R_1}{R_2} \times \frac{K_1}{K_2} \times \frac{A_1\,(t_0)}{A_2\,(t_0)}$$

where R_1 and R_2 are the response factors of the two components; K_1 and K_2 are the respective partition coefficients; $A_1\,(t_0)$ and $A_2\,(t_0)$ are the areas of the peaks obtained at time (t_0), (t_0) being the time at which the sample starts to decay from the system. Such values of A are produced by the linear extrapolation of any two log area measurements against decay time, back to time (t_0) (Fig. 1).

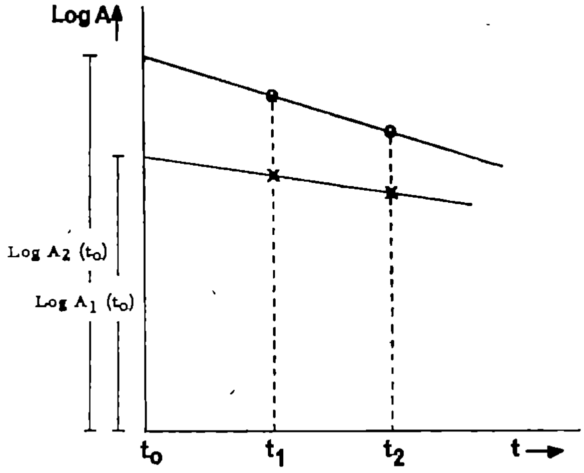

Fig. 1

K_1/K_2 may be obtained from the ratio of the retention times of the two peaks measured from the air peak and R_1/R_2 may either be known or be determined from a similar run where M_1/M_2 is known.

A further interesting aspect of the system is that original samples may be diluted in this manner and the exit gas sampled at times so chosen that the two chromatograms are preferentially enriched in any minor constituent which may be of particular interest; such enrichment obviously results in a more accurate determination of that component. Thus, for the accurate evaluation of trace amounts of substances with low partition coefficients the two gas samples should be taken after small values of t, and the size of the gas sample taken from the dilution system should be small. Conversely, for determining trace amounts of substances with high partition coefficients the values of t should be large, and the size of the gas sample taken from the dilution system should be increased.

The system described here has been developed as a result of a recent improvement in the original vapour dilution technique described by Dr. J. E. Lovelock[1]. Such improvements are described in a paper to be published shortly by I. Fowlis and R. P. W. Scott.

Effect of Fluoride Ion on the Activation of Molecular Hydrogen by Silver(I)

ACCORDING to Halpern[1] the effect of complex forming ligands on the activation of molecular hydrogen by metal ions can be explained by the following scheme:

$$\begin{array}{cc} M^+ & \!\!—X^- \\ \vdots & \vdots \\ H^- & \!\!—H^+ \end{array}$$

Thus the heterolytic splitting of hydrogen is the consequence of the concerted action of the central metal ion and the ligand bond. Great activation effect can be expected from the ligands which, although weak acids, form unstable complexes with the metal ion, that is, which do not screen the positive charge partly responsible for the heterolytic splitting. These requirements are contradictory in general, being a parallelism between the proton affinity and the complex forming tendency of the ligands. In the case of silver(I), the reduction of which by hydrogen was thoroughly investigated by Halpern *et al.*[2-4], the fluoride ion fulfils the requirements mentioned: although hydrogen fluoride is a rather weak acid ($pK = 3{\cdot}4$), the fluoride ion forms an unstable monofluorosilver(I) complex[6,7].

So the effect of fluoride ion on the reduction of silver(I) by molecular hydrogen seemed worthy of investigation.

The reaction was studied in an all-glass apparatus. Hydrogen was bubbled through the thermostatically controlled neutral solution (pH 6) of silver nitrate (up to 0·1 mole/l.) and potassium fluoride (up to 2·0 mole/l.). The reaction was followed by the titrimetric determination of non-reduced silver(I).

The fluoride ions increase dramatically the velocity of reduction. The results can be described by the following expression:

$$-\frac{d[H_2]}{dt} = \frac{1}{2}\frac{d[Ag^+]}{dt} = v = k.C_{Ag}\frac{K[F^-]}{1+K[F^-]}.[H_2]$$

where K is the stability constant of the silver fluoride complex[7]. Light has a small but definite enhancing effect. The velocity constants were calculated at different temperatures in the range of 30–70° C. The results are summarized in Table 1. For comparison some literature data referring to the aquo-complex and to the most effective amine complexes are also included.

Table 1

Ligand	log k (70° C)	$\Delta H^{\ddagger}$	$\Delta S^{\ddagger}$
H_2O	−3·2	23·3	− 6
CH_3–$N(CH_2$–$CH_2)N(CH_3)_2$	0·17	15·1	−14
$N(CH_2CH_2)_3N$	0·26	17·1	− 8
F^- (in dark)	0·79	18·3	− 3
F^- (in diffused daylight)	0·88	20·3	+ 4

Thus the fluoride ion is the most effective ligand so far found.

Considering that the configuration of silver(I) complexes is linear, and that the co-ordinated F^- and H_2 do not touch each other even being in adjacent position, the following scheme for the activated complex must be assumed:

Steric Effect in Mass Spectra of *cis–trans* Disubstituted Ethylenes

PREVIOUSLY[1-5] we reported results concerning the behaviour under electron impact of *cis* and *trans* isomers of disubstituted cycloalkanes. The steric effect in such compounds shows up by the fact that the ionized *cis* isomer is less stable than the corresponding *trans* one in derivatives of *cyclo*propane[1], *cyclo*butane[2], *cyclo*pentane[3] and *cyclo*hexane[4]. Those results are summarized in a recent paper[5].

In the same way we have investigated several pairs of *cis* and *trans* ethylenic isomers in order to check whether the same kind of relationship exists between mass spectra and stabilities of those isomers. Looking up the few data published in the literature[6] we found six pairs of *cis–trans* derivatives of butene with an increasing number of methyl groups on the two end carbon atoms.

We calculated the abundances I_{cis} and I_{trans} of molecular ions in percentage of total ionization. The results are listed in Table 1. These can be considered as a measure of the stability of the ionized compounds[7].

The figures in the last column of Table 1 indicate that within experimental uncertainties there is no difference between the stabilities of *cis* and *trans* 2-butenes. The same situation occurs in derivatives of butene substituted by one methyl group (2-pentene) or by two methyl groups,

Table 1. RELATIVE ABUNDANCES OF MOLECULAR IONS IN *cis–trans* DISUBSTITUTED ETHYLENES (PERCENTAGE TOTAL IONIZATION)

Pair No.	Name of the compound	Formula*	I_{trans}	I_{cis}	I_{trans}/I_{cis}
1	2-Butene	C—C=C—C	17·98	18·11	0·99
2	2-Pentene	C—C=C—C—C	9·71	9·62	1·01
3	4-Methyl-2-pentene		8·08	7·98	1·01
4	3-Hexene	C—C—C=C—C—C	6·97	6·85	1·02
5	4,4-Dimethyl-2-pentene		6·52	5·96	1·09
6	5,5-Dimethyl-3-hexene		4·19	3·42	1·22
7	2,2,5,5-Tetramethyl-3-hexene		1·08	0·16	≃ 7

* H atoms omitted.

either on the same end carbon atom (4-methyl-2-pentene) or on both of them (3-hexene).

If one of the end carbon atoms of butene is substituted by three methyl groups (4,4-dimethyl-2-pentene), the abundance of the *cis* isomer becomes 10 per cent smaller than that of the *trans* isomer. A further substitution by a methyl group again decreases the abundance of the *cis* isomer by about another 10 per cent (5,5-dimethyl-3-hexene). In the last butene derivative which has six methyl groups on the two end carbon atoms (2,2,5,5-tetramethyl-3-hexene) a tremendous effect shows up since the *trans* isomer molecular ion is about 7 times more abundant than the *cis* isomer.

As a result, one must emphasize that the substitution of ethylene by a tertiary butyl group has an obvious effect on the stability of the *cis* isomers, especially in the last compound. This has to be related in some manner to the steric hindrance provided in the *cis* molecule when such a close-packed group exists in it.

It is likely that the ionization is produced by removal of one of the non-bonding π electrons of the double bond. Consequently the isomerism should disappear in the ionized molecule and the energy provided by steric hindrance would be released and used for further decomposition. Therefore, in the *cis* isomer of the last three pairs where steric hindrance is especially large because of the tertiary butyl group, the stability of the ionized molecule has to be smaller than that of the *trans* isomer.

This result is quite similar to that found in the case of cyclanic isomers previously investigated.

It may also be interesting to notice that there is a regular decrease in the abundance of molecular ions, in either *cis* or *trans* isomers, when the number of methyl groups fixed on the end carbon atoms of butene is increasing. The same rule was observed in the alkane series.

I thank Prof. L. D'Or for his interest in this work. I also thank the Fonds National de la Recherche Scientifique for supporting this work.

Hydrogen and Chlorine Hyperfine Splittings of Several 2-Hydroxy-1,4-naphthosemiquinones

RECENTLY, Hollocher and Weber[1] published electron spin resonance spectra of alkaline aqueous systems containing partially reduced 2-hydroxy-3-methyl-1,4-naphthoquinone (I), but did not identify the radical responsible.

We now give evidence that the semiquinone of (I) is responsible for the observed spectra. Comparisons among the spectra obtained with the foregoing system and with similar systems containing other 2-hydroxy-1,4-naphthoquinones indicate that the apparent complexity of the hyperfine structure arises from a non-equivalence of the four benzenoid ring protons to give three different splittings with consequent overlapping of individual lines.

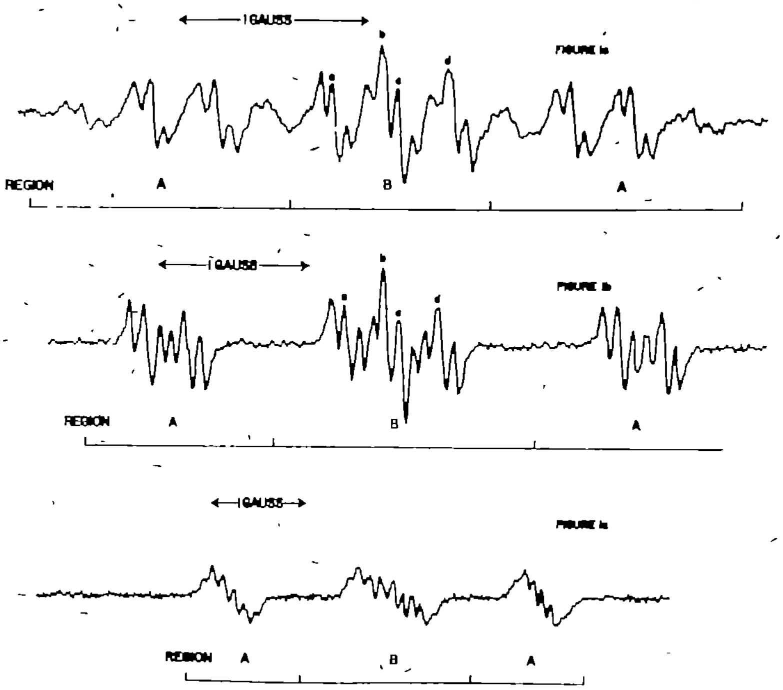

Fig. 1. First derivative electron spin resonance spectra in alkaline aqueous media of the semiquinones of: *a*, 2-hydroxy-3-methyl-1,4-naphthoquinone; *b*, 2-hydroxy-1,4-naphthoquinone; *c*, 2-hydroxy-3-chloro-1,4-naphthoquinone. Field increases from left to right

The striking differences between the electron spin resonance spectra of the semiquinones of 2-hydroxy- and 2-hydroxy-3-chloro-1,4-naphthoquinones (II and III) are interpreted as proof of resolved chlorine hyperfine splitting in the latter compound.

Electron spin resonance observations were made at room temperature using a Strand Lab 602 spectrometer with *2K25* klystron operating at the cavity resonance frequency of 9·5 kMc/s and with modulation frequency of 6 kc/s. The field was generated by a Harvey Wells system including *L*-128 12-in. magnet and model *HS*-1050 power supply.

Field positions and separations were obtained using sodium carbonate solutions of potassium peroxylamine disulphonate or calcium xanthon in tetrahydrofuran.

Modulation amplitudes were 20 milligauss or less at a non-saturating microwave power-level at the sample of 1 mW or less. Field was swept at a rate of 1–2 gauss/min using a time-constant of 0·15 sec. Sample dimensions were 0·8 mm diameter × 35 mm long, and the apparent field inhomogeneity over the sample was about 3 parts in 10^6.

Compounds (I) and (II) were commercial preparations repurified before use. (III) was prepared after the method of Zincke[2] by heating naphthoquinone epoxide with 4 N hydrochloric acid, m.p. 216° C.

For preparation of the naphthosemiquinones, the naphthoquinones were dissolved in 0·1 N potassium hydroxide to give a final concentration of 10^{-3} M or less. Following reduction by sodium dithionite, the excess dithionite was removed and the compounds were partially re-oxidized by contact with air. Once formed, the radicals were found to be stable indefinitely at room temperature in an oxygen-free environment.

All hyperfine splittings reported are estimated to be ± 5 per cent of the value.

Figs. 1*a*, 1*b* and 1*c* show representative first derivative electron spin resonance spectra of partially reduced (I), (II) and (III), respectively, in alkaline aqueous solution at room temperature. Observed line widths are 0·02 to 0·04 gauss and the *g* values are 2·004 ± 0·0005 in each case.

In region *A* of Fig. 1*b* we observe a pair of triplets with splitting of 0·10 gauss and 0·28 gauss and intensity ratios of 1 : 1 for the pair of triplets and 1 : 2 : 1 within each triplet. Ten lines are found in region *B* of Fig. 1 and the splitting of 0·10 gauss is exactly or closely maintained between the lines. Considering the four strongest lines, *a*, *b*, *c*, and *d*, in this region we find the distance *a–b* and *c–d* to be 0·28 gauss.

The basic structure of this spectrum is interpreted to consist of four lines and the distance *a–c* or *b–d* (0·39 gauss) is a measure of the failure of the middle two of these lines to superimpose to form a triplet. The splittings of the two protons responsible for this basic structure are 1·48 and 1·87 gauss. These splittings and those above account for all five protons of the semiquinone of (II).

In (I) a methyl group replaces a hydrogen to give two additional hydrogen atoms to participate in hyperfine splitting. In Fig. 1*a* we observe a spectrum[1] closely analogous to that of Fig. 1*b* showing the additional hyperfine splitting due to the methyl hydrogens. In region *A* of Fig. 1*a* there is a quartet of triplets with the innermost member of the quartet partially obscured by overlapping minor lines extending outward from region *B*. The splittings are 0·35 gauss for the quartet and 0·08 gauss for the triplets. Intensity ratios for the quartet are 1 : 3 : 3 from the outermost inward, neglecting the obscured innermost member on each side, while those for the triplets are 1 : 2 : 1.

For the ten clearly observable lines in region *B* the separation of 0·08 gauss is closely or exactly maintained. The four strongest lines *a*, *b*, *c* and *d* are so disposed that *a–c* and *b–d* are 0·35 gauss. Thus, by analogy with Fig. 1*b*, the distance *a–b* or *c–d* (0·25 gauss) is a measure of the failure of the two middle lines of the basic four-line spectrum (the splittings for which are 0·98 and 1·23 gauss) to superimpose. This interpretation accounts for all seven hydrogen atoms of the semiquinone of (I) and give one set of three equivalent protons (methyl) and, as with (II), another set of two equivalent protons.

The spectrum depicted in Fig. 1*c* shows an unexpected detail. By analogy with (I) and (II) and assuming no observable hyperfine splitting by the chlorine atom, we anticipated with (III) a triplet in region *A* and up to six lines in region *B*. The actual spectrum shows six lines in region *A* with separations of 0·12 gauss and nine lines in region *B* with the same separations. For the six lines, the integrated intensity ratios of 1 : 2·8 : 4·1 : 4·1 : 2·8 : 0·9 approximate the ratios of 1 : 3 : 4 : 4 : 3 : 1 expected of a 3 × 4 splitting of a proton triplet by a chlorine atom to an amount equal to the proton splitting. This observation, and other features of the spectrum, are interpreted to evidence the existence of resolved chlorine hyperfine splitting in the semiquinone of (III). The magnitude of the splitting indicates that the spin density at the chlorine nucleus in the case of (III) is of the same order of magnitude as that at the corresponding methyl or ring proton in the case of (I) and (II). To our knowledge this is the first observation of resolved chlorine hyperfine splitting in organic radicals. We attribute the successful resolution to the low radical concentrations utilized since the lines broaden considerably at higher concentrations.

The remainder of the spectrum is interpreted in the manner described here and the hyperfine splittings for all three spectra are summarized in Table 1.

Table 1. SUMMARY OF HYPERFINE SPLITTINGS

Nuclear species	No. of equivalent nuclei	Ring designation	Splittings in gauss ± 5 per cent (I) 2-Hydroxy-3-methyl-1,4-naphthoquinone	(II) 2-Hydroxy-1,4-naphthoquinone	(III) 2-Hydroxy-3-chloro-1,4 naphthoquinone
H	2	benzenoid	0·08	0·10	0·12
Cl	1	quinoid 3-	—	—	0·12
H	1	quinoid 3-	—	0·28	—
H	3	quinoid 3-methyl	0 35	—	—
H	1	benzenoid	0·98	1·48	1·56
H	1	benzenoid	1·23	1·87	1·90

It will be noted that the hyperfine splittings for the 2-hydroxy-naphthosemiquinones studied are quite different from those reported for methyl and alkyl substituted 1,4-benzo- and naphthosemiquinones[2–7]. For these latter compounds the splittings are: quinoid ring and methyl protons about 2·2 gauss and methylene protons about 1·1 gauss; benzenoid ring protons about 0·5 gauss. The presence of the ionizable hydroxyl function in the 2-position decreases the spin density at the 3-proton or 3-methyl protons by a factor of 6–8 and renders the 5-, 6-, 7- and 8-protons of the benzenoid ring non-equivalent, giving one nearly equivalent pair with strong splitting of order 1–2 gauss and one equivalent pair with weak splitting of order 0·1 gauss.

Work is continuing to confirm the placing of these two pairs of protons in the benzenoid ring.

BIOCHEMISTRY

Enzymatic Behaviour of the Product of Coenzyme A–Norepinephrine Reaction

REACTION of the sulphydryl group of coenzyme A *in vitro* with oxidation products of epinephrine and norepinephrine has been demonstrated by chemical measurement of the residual —SH groups[1]. The coenzyme A–catecholamine compounds may well represent an important stage in intermediary metabolism, since their breakdown may lead to regeneration of coenzyme A and formation of physiologically active catecholamine derivatives. Furthermore, if coenzyme A is inactivated by these reactions, an explanation may be at hand for some of the physiological effects of the catechol amines. The work reported here evaluates the reactivity and stability of the coenzyme A–catecholamine derivatives in the light of their enzymatic activity *in vitro*.

The reduced form of coenzyme A comprised 75–80 per cent of the preparation obtained from the Nutritional Biochemical Corporation, according to the catalogue, while approximately 10 per cent consisted of glutathione and the remaining 10 per cent of oxidized coenzyme A. The preparation was described as hygroscopic. During experimental manipulations, the coenzyme had an opportunity to bind atmospheric water. The sulphydryl group found in the weighed preparation by the method of Ellman[2] was equivalent, disregarding the glutathione, to 44 per cent of reduced coenzyme A. Tyrosinase, phosphotransacetylase, and dilithium acetyl phosphate were obtained from the Worthington Biochemical Corporation, Freehold, New Jersey.

The Lipmann technique[3] for determination of coenzyme A was used. Separate solutions contained 0·31 × 10^{-3} M coenzyme in water and 1,170 μg of tyrosinase per ml. of 0·1 M *tris* buffer of *p*H 7·4. Tubes containing 0·5 ml. aliquots of phosphotransacetylase were stored in a freezer. Immediately before use, the contents of one tube were diluted 1 : 10 with water. A tube containing 60 μM of dilithium acetyl phosphate in 1 ml. of water was simultaneously removed from the freezer. The concentration of

Table 1. ABSORBANCY AT 510 mμ OF SOLUTIONS CARRIED THROUGH THE PROCEDURES INDICATED IN THE TEXT. 0·28 × 10^{-6} MOLES OF COENZYME A WERE IN EACH TUBE INITIALLY

No Co A	0·570
Co A alone	0·167
Co A, 0·30 × 10^{-6} moles norepinephrine	0·556
Co A, 0·20 × 10^{-6} moles norepinephrine	0·425
Co A, 0·10 × 10^{-6} moles norepinephrine	0·305

norepinephrine in 0·01 N hydrochloric acid was 0·30 × 10^{-3} M. The reaction between coenzyme A and an oxidation product of norepinephrine proceeded at 28° C in separate tubes, each of which ordinarily contained 0·9 ml. of coenzyme A, norepinephrine, 0·6 ml. of tyrosinase, and water to a total volume in each tube of 2·1 ml. Six min. later, 0·5 ml. were removed from each tube and started through the rest of the Lipmann procedure[3]. The absorbancy was measured at 510 mμ in the Beckman spectrophotometer, with water as the blank.

Typical results are presented in Table 1. The decrease in the colour produced from acetyl phosphate was directly proportional to the amount of coenzyme A present. Tyrosinase had no effect in the absence of the catecholamine. The relatively large amount of tyrosinase oxidized the norepinephrine within 5 min. The reaction of coenzyme A with an oxidation product of norepinephrine led to an increase in the residual amount of acetyl phosphate. The amount of coenzyme A activity left after reaction on an equimolar basis with various concentrations of the norepinephrine derivative was closely consistent with the initial amount of the coenzyme calculated from the measured sulphydryl group.

The inability of the coenzyme A which had reacted with an oxidation product of norepinephrine to combine with the acetyl phosphate in the Lipmann technique confirmed that the enzymatically active sulphydryl group was the reaction site. It demonstrated also the stability of the coenzyme A–catecholamine product in an enzymatic environment *in vitro*.

This investigation was supported by grant No. *M*–2795 (*C*I) from the National Institutes of Health, U.S. Public Health Service.

Carbonic Anhydrase in Bacteria

THE richest source of carbonic anhydrase is mammalian erythrocytes. It is also found in the pancreas, gastric mucosa, and kidney in fairly high concentration. Carbonic anhydrase has also been found localized in the cytoplasm of plant leaf tissue[1–4]. A survey of the literature revealed no report of the occurrence of microbial carbonic anhydrases. Main and Lock[5] reported that Type I *Pneumococcus* and *Staphylococcus aureus* did not produce carbonic anhydrase.

One of us (F. P. V.) had noted some carbonic anhydrase activity in the nasal exudates of persons suffering from respiratory infections. This carbonic anhydrase activity could have been from several sources: (1) from erythrocytes arising from ruptured capillaries; (2) from the tissues involved; (3) or possibly from bacteria of the normal naso-pharyngeal flora. It therefore seemed of interest to examine some of the ubiquitous oral and naso-pharyngeal micro-organisms for carbonic anhydrase activity.

Nine cultures of *Neisseria* (*N. catarrhalis*, strains No. 8716 and *N*9; *N. flava N*8; *N. perflava* 231*D*; *N. subflava N*15; *N. sicca*, strains Nos. 6021, 22, 19 and *N*5), a species of *Lactobacilli* (*L. acidophilus* No. 926), and a strain of *Streptococcus salivarius* were examined for carbonic anhydrase activity. (All *Neisseria* cultures were given by Prof. Michael J. Pelczar, Department of Microbiology, University of Maryland, and the *Lactobacilli* and *Streptococcus* were obtained from the stock culture collection of the Department of Microbiology, University of Maryland.)

The *Neisseria* and *Streptococci* were grown on trypticase-soy agar (B.B.L.) whereas *Lactobacilli* were grown in deep broth cultures of trypticase-soy broth to which was added 0·5 per cent (w/v) yeast extract (B.B.L.), 0·05 per cent (w/v) cysteine hydrochloride, and sufficient 1·0 N hydrochloric acid to adjust the *p*H to 6·5. All media were sterilized by autoclaving at 121° C, 15 p.s.i. for 20 min. All cultures were incubated at 37° C for 48 h.

Cells were collected from agar plates by washing off the growth with distilled water; broth cultures were collected by centrifugation. All cell crops were washed three times with glass distilled water and finally suspended in sufficient distilled water to make a dense suspension. Fresh suspensions were prepared for each day's experiment. Dry weight of the various suspensions was determined by drying 3 ml. of each in small beakers in an oven for 24 h at 95° C, followed by a 30-min cooling period in a desiccator prior to weighing.

A crude chloroform enzyme preparation was produced from horse erythrocytes according to the method of Meldrum and Roughton[6]. This preparation will be referred to as 'horse enzyme', and was used for comparison with bacterial cell suspensions and evaluation of the assay method. It was stored in a stoppered Erlenmeyer flask at 3° C. Dry weight was determined in the same manner as outlined here for bacterial cell suspensions.

Enzyme activity was measured manometrically as evolution of carbon dioxide resulting from dehydration of carbonic acid after the method of Krebs and Roughton[7]. Reaction flasks were charged as follows: 1·0 ml. 0·10 M K_2HPO_4–KH_2PO_4 *p*H 6·8 buffer, and 1·0 ml. appropriate enzyme preparation (or 1·0 ml. distilled water in buffer controls) in the main compartment; 1·0 ml. 0·05 M sodium bicarbonate (substrate) in arm 1. In flasks utilized to determine endogenous oxygen uptake 0·2 ml. 20 per cent potassium hydroxide was included in the centre well. A 10-min temperature equilibration period was followed by a 5-min leak-check period before the reactions were begun. Flasks were shaken at the rate of 120 strokes/min. All reactions were carried out at 24·9° C for 4 min and observed at 30-sec intervals. Samples of *N. sicca* suspensions were heated in test-tubes for 10-, 15-, and 20-min periods at 100° C in a boiling water bath to determine if observed activity was enzymatic.

The activity of each preparation expressed in terms of carbon dioxide evolved per mg dry weight per 60 sec is given in Table 1. *N. sicca* strain No. 6021 showed activity which was almost as high as the horse enzyme. Other strains of *N. sicca* also had measurable activity. Other bacteria tested showed little or no activity.

Table 1. A SUMMARY OF BACTERIAL AND HORSE ERYTHROCYTE CARBONIC ANHYDRASE ACTIVITY BASED ON DRY WEIGHT AND CORRECTED FOR BUFFER CONTROL

Preparation	μl. CO_2 evolved per mg dry weight per 60 sec = $Q_{dw}CO_2$*
Horse enzyme	8·31, 8·79
N. catarrhalis 8716	0·75
S. salivarius	0·69
*N. flava N*8	0·75
*N. catarrhalis N*9	0
N. perflava 231*D*	1·74
N. sicca 6021	7·90, 7·86, 8·05, 7·70
*N. subflava N*15	0
L. acidophilus 926	0
N. sicca 22	2·84
*N. sicca N*5	0
N. sicca 19	3·00
N. sicca 6021 Boiled 20 min	1·12

* Values are averages of two or more trials.

Flasks shaken in 24·9° C water bath contained 1·0 ml. 0·1 M K_2HPO_4–KH_2PO_4 *p*H 6·8 buffer and 1·0 ml. appropriate enzyme preparation (1·0 ml. water in buffer control) in the main compartment, 1·0 ml. 0·05 M sodium bicarbonate in side-arm 1.

The established role of carbonic anhydrase[4] in fluid and ion exchange processes tempts one to speculate on a possible relation between the presence of this enzyme in the ubiquitous microbial inhabitants of the naso-pharynx and the symptoms of the common cold. Two possibilities immediately present themselves. (1) Carbonic anhydrase is present in these organisms and plays a part in the excretion of certain products of microbial metabolism: that is, acids, and/or the ill-defined slimes known to be produced[9]. These excretory products could in turn irritate the mucous membranes of the naso-pharynx altering their permeability and susceptibility to invasion. (2) The presence of extra-cellular carbonic anhydrase could disturb the normal excretory mechanism of the mucous membrane tissue cells themselves, leading to changes in permeability and resistance to invasion. We find these two postulated mechanisms intriguing and intend further studies in this area.

Unusual Behaviour of a Mammalian Collagen in Deuterium Oxide

GROSS[1] observed that heating a solution of collagen in phosphate buffer to 37° C resulted in the formation of an opaque gel of collagen fibres. That this occurred at 37° C, but not in the cold, suggests that some unfolding of the collagen molecule is required to form fibres or gels, and that newly synthesized collagen molecules, *in vivo*, are also not as highly ordered as possible, but are somewhat unfolded in order to form connective tissue fibres. To test this idea *in vitro* we proposed to conduct the Gross heat gelation in deuterium oxide. Harrington and von Hippel[2] showed that in the case of ichthyocol collagen in deuterium oxide, the helix→coil transition occurs at a temperature 4° C higher than in water. If heat gelation of collagen in deuterium oxide were to require a higher temperature than in water, the hypothesis would be supported. When we attempted to carry out the experiment, unexpected results were obtained, of which a preliminary report is presented here.

Soluble collagen was obtained from rabbit skin by extraction at 5° C with two changes of 0·5 M sodium acetate, followed by citrate buffer of *p*H 3·5. The citrate solution was dialysed against *p*H 7·6 phosphate buffer and distilled water to yield collagen fibres which were collected by centrifugation, washed three times with distilled water and freeze-dried for storage.

Solutions of collagen were made and treated as shown in Table 1. Electron micrographs of the fibres *D* showed them to be about 500 Å wide and unstructured. It is of interest that after dialysis against water–phosphate fibres did not form on dialysis against deuterium oxide–phosphate (*C*), although in the original preparation the collagen had been dialysed against aqueous phosphate, although of a different strength and *p*H.

When *B* was slowly warmed the opaque gel of Gross[1] began to form at 35° C, and finally disappeared at 52° to give a clear gelatin solution. When *C* was heated, the opaque gel began to form at 25° C and finally disappeared at 56°. The range of existence of the deuterium oxide gel is thus 14° larger than that of the water gel, a remarkably large protein deuterium effect. Solutions *B* and *C* gave single hypersharp peaks in the ultracentrifuge.

Table 1. BEHAVIOUR OF COLLAGEN IN DEUTERIUM OXIDE AND WATER BUFFERS (0·04 M SODIUM DIHYDROGEN PHOSPHATE, 0·09 M DISODIUM HYDROGEN PHOSPHATE, *p*H 7·2) AT 5° C

0·2 per cent collagen in 0·5 M acetic acid in water or deuterium oxide, solution *A*	
A dialysed against water-phosphate buffer to yield clear, viscous solution *B* *B* dialysed against deuterium oxide–phosphate to yield clear, viscous solution *C*	*A* dialysed against deuterium oxide–phosphate buffer to yield fibres, *D*. Larger yield of fibres when *A* is made in deuterium oxide

When collagen in aqueous citrate buffer (0·1 M sodium citrate, *p*H 4·3) was heated, it merely became converted to gelatin on reaching about 40° C, as indicated by a large decrease in viscosity. However, in deuterium oxide–citrate the solution became turbid at 25° C, then opaque at about 29° C and deposited fibres.

Possible slight differences of acidity between the water and deuterium oxide solutions have been ignored so far. Both heat gelation[1] and denaturation in acid citrate[3] are known to be insensitive to such small *p*H differences. After the initial observations were made, we carried out the next experiments with deuterium oxide double-distilled from permanganate; identical results were obtained. Nevertheless, we are using purified deuterium oxide in all the present work.

We are carrying on an extensive investigation of the chemical and physical properties of various collagens in deuterium oxide, and of fibres conditioned with deuterium oxide. This solvent is also being used to extract collagen and other macromolecules from biological sources.

We thank Mr. William Kimber for preparing the collagen, Mr. Franklyn Wissler for the ultracentrifuge runs and Drs. Melvin Glimcher and Dorothy Travis of the Massachusetts General Hospital for electron micrographs.

Cholesterol Esters of the Cockroach *Eurycotis floridana*

INVESTIGATIONS of the metabolism and occurrence of sterols in insects have led to several reports of the presence of sterol esters in these organisms[1–3], and some observations concerning the characteristics of a sterol esterase in at least one species of cockroach have been recorded[1]. Up to the present time, however, no work on the constitution of the sterol esters of an insect has been described. We have undertaken such a study in relation to a broader investigation of the functions of sterols in the cockroach, *Eurycotis floridana*, and some of our preliminary findings are reported here.

The cockroaches used in this work were reared aseptically by the technique which has been described[4]. Materials from insects reared on three diets of distinctly different fatty acid content were analysed. Diet 1 was that which is used routinely in our laboratory and consisted of the semi-synthetic diet of Noland and Baumann[5], in which the corn oil was replaced by commercial sodium oleate. Diet 2 was identical with diet 1, except that the corn oil was replaced by a mixture of saturated fatty acids. Diet 3 was a commercially available dog food. The individual fatty acid components of these diets are given in Table 1 as percentages of the total fatty acid present.

Table 1. STEROL ESTERS OF THE COCKROACH, *Eurycotis floridana*, REARED UNDER VARYING DIETARY CONDITIONS

Diet	Percentage composition* of dietary fatty acids		Percentage composition of cholesterol esters of the insect Saturated	Mono-unsaturated	Di-unsaturated
1	Palmitic	9·9	1·3	82·0	16·7
	Stearic	1·9			
	Oleic	79·0			
	Linoleic	2·9			
	Others	6·3			
2	Palmitic	29·9	8·8	81·4	9·8
	Stearic	26·4			
	Arachidic	24·8			
	Docosanoic	12·2			
	Others (saturated)	6·7			
3	Palmitic	26·8	3·8	82·3	13·9
	Stearic	12·3			
	Oleic	39·3			
	Linoleic	11·6			
	Others	10·0			

* Calculated as: $\dfrac{\text{Peak height} \times \text{distance of peak from injection point}}{\text{Sum of such products for all peaks detected}}$

These values were determined by gas-liquid chromatographic analysis of the methyl esters prepared from the fatty acid additives of diets 1 and 2, and from the saponifiable fraction of diet 3. Identification of the peaks in these gas-liquid chromatograms and in others to be described was based on retention times and comparison with known standards. Diets 1 and 2 each contained 0·1 per cent 4-[^{14}C]-cholesterol, specific activity 4,140 d.p.m. per µg. 4-[^{14}C]-cholesterol was added to diet 3 to give a final specific activity greater than that of the sterol in diets 1 and 2.

As a general procedure for the isolation of sterol esters, the insects were chilled in ice and dissected as rapidly as possible into cuticle and soft tissues, from which the gut contents were carefully excluded.

The hard and soft tissues were separately extracted to remove the total lipids, and a crude sterol ester-fraction was isolated in each case by chromatography of the lipids on silicic acid, according to Barron and Hanahan[6]. This material was then fractionated into its component esters by a second chromatography on silicic acid by the method of Klein and Janssen[7].

Gas-liquid chromatography[8] of the methyl ether of the crude sterol isolated from the tissues of insects reared aseptically on diet 1 showed cholesterol to be the only sterol present. Attention was therefore focused on the identification of the fatty acid moieties of the sterol esters.

By the chromatographic procedure of Klein and Janssen, the sterol esters are eluted in order of increasing desaturation of the fatty acid chain and may be tentatively identified on the basis of their elution volumes. When chromatographed in this way, sterol esters of the insects were always eluted as three peaks, corresponding in relative elution volume to the esters of saturated, mono-unsaturated and di-unsaturated fatty acids, respectively, which together generally accounted for more than 90 per cent of the radioactive material applied to the column. These tentative identifications were confirmed with insects raised on all three diets by co-chromatography of their crude [^{14}C]-sterol esters with trace amounts of synthetic 3α-[^{3}H]-cholesteryl oleate and linoleate, followed by simultaneous assay of the eluant fractions for tritium and carbon-14. The two isotopes in the mono-unsaturated and di-unsaturated fractions were consistently recovered as coincident peaks extending over approximately 40 and 60 fractions respectively, indicating the possible identity of the main biological [^{14}C]-esters with the two added tracer substances.

The relative abundance of each type of ester found in the tissues of the insects is shown in Table 1. These values were calculated from the ^{14}C content of individual peaks as a percentage of the total carbon-14 recovered in all three peaks in the chromatography according to Klein and Janssen. This chromatographic evidence suggests that a similar pattern of cholesterol esters occurs in the insects reared on all three diets. The appearance of a large proportion of unsaturated esters of cholesterol in insects reared on diet 2, in which the fatty acids are entirely saturated, is consistent with our finding that unsaturated fatty acids are synthesized in this insect under the experimental conditions used[9].

Since our primary object was to identify the sterol esters present in the tissues of cockroaches reared under our routine conditions with diet 1, a more searching analysis of the sterol esters isolated from these insects was undertaken. Soft tissues weighing 2·8 g from twelve insects reared on diet 1 yielded 4·16 mg crude 4-[^{14}C]-cholesterol esters, the carbon-14 content of which indicated the presence of approximately 3·5 mg cholesterol esters, calculated as oleate. This material was divided into two portions, each of which was separated into its three component ester fractions in the manner indicated here. The fractions corresponding to the mono-unsaturated and di-unsaturated esters from one portion were combined with pure synthetic unlabelled cholesteryl oleate and linoleate, respectively, and recrystallized repeatedly with measurement of the specific activity after each crystallization. The oleate showed no loss of radioactivity after 5 recrystallizations (found 34·8; calc. 34·2 d.p.m. per µg), indicating the presence of 100 per cent of the label of the biological material in cholesteryl oleate. The linoleate, on the other hand, lost 26 per cent of the original activity in a similar series of crystallizations (found 8·2; calc. 11·1 d.p.m. per µg), indicating a maximum of 74 per cent cholesteryl linoleate in the di-unsaturated cholesterol esters of the insect.

The three ester fractions isolated from the second portion of this material were separately saponified and the fatty acids extracted, converted to their methyl esters by treatment with diazomethane, and analysed by gas-liquid chromatography under conditions which have been described[10]. All reagents and equipment used in the initial chromatography of this material and in the preparation of the methyl esters were specially treated to eliminate contaminants which otherwise produced spurious peaks in the gas-liquid chromatograms.

The results of these analyses supported the evidence of co-crystallization in showing that 99·5 per cent of the acid from the mono-unsaturated ester peak could be accounted for as oleate and that the major component (90·6 per cent) of the di-unsaturated ester fraction could be accounted for as linoleate. Other acids detected in the latter fraction were stearate (3·1 per cent), oleate (3·4 per cent), and possibly traces of palmitate, palmitoleate, myristate and other unknown materials. The 'saturated' ester fraction contained palmitate (43·1 per cent) and stearate (10·8 per cent) as the principal saturated acids and oleate (23·6 per cent) and palmitoleate (19·3 per cent) as mono-unsaturated contaminants.

The discrepancy between the values for the linoleate content of the di-unsaturated fraction, as shown by co-crystallization and by gas-liquid chromatography, may be due to varying degrees of cross-contamination of the major sterol ester fractions which we have observed to occur under some conditions during chromatography by the technique of Klein and Janssen. The appearance of unsaturated acids in the 'saturated' fraction may be due to the same cause. Whether these contaminants are always derived from the corresponding sterol esters is not known.

Further evidence for the identity of the oleate and linoleate esters was obtained by oxidative degradation of the acids isolated after saponification of the appropriate sterol ester fractions, which were obtained in this instance from the cuticle of insects raised on diet 1. The acids were oxidized by a micro-modification of the method of van Rudloff[11] to yield, in each case, a dicarboxylic acid representative of that part of the fatty acid chain lying between the carboxyl group and the double bond closest to it. Gas-liquid chromatography of the methyl esters of the oxidation products showed that a C9 acid was almost the sole dicarboxylic acid formed, a finding which is consistent with the proposed structures of the fatty acid moieties of the sterol esters.

The results so far obtained in this work leave little doubt that the major sterol ester of *E. floridana* reared on diet 1 is cholesteryl oleate. The remaining sterol esters appear to consist principally of linoleate and a small saturated ester fraction in which palmitate is the principal component. Further work is in progress to determine whether there is any consistent influence of the diet on the proportions of the various cholesterol esters in this insect.

We thank Prof. Konrad Bloch, in whose laboratory this work was carried out, for his continued interest and encouragement. One of us (R. B. C.) is an established investigator of the American Heart Association. This work was supported by grants from the American Heart Association and the U.S. National Institutes of Health.

Phospholipid Composition and Turnover in Rat Intestinal Mucosa during Fat Absorption

SINCLAIR[1] suggested in 1929 that phospholipids are obligatory intermediates in the absorption of fat. Later work by Zilversmit, Entenman and Chaikoff[2] indicated, however, that there is little or no increase in turnover of the gross phospholipid fraction during absorption. Johnston and Bearden[3] recently obtained evidence that a minor component, phosphatidic acid, has increased turnover during fat absorption *in vitro*. It seemed important, therefore, to examine the turnover of individual mucosal phospholipids during fat absorption *in vivo*, with special reference to phosphatidic acid.

Rats, previously starved for periods of about 15 h, were fed with 0·75 ml. of olive oil, by stomach tube. A period of 2 h was allowed for absorption to proceed and the animals were then injected intravenously with 1 mc. carrier-free NaH$_2$^{32}PO$_4$ in 1 ml. of 0·9 per cent sodium chloride. Half an hour after the injection of the isotope, the animals were killed, the intestine removed and the contents of the small intestine, stomach and caecum irrigated with 0·9 per cent sodium chloride. The excess fat was extracted from these washings and related to the amount fed. The mucosal cells were then scraped off and immediately homogenized in ice-cold 10 per cent trichloroacetic acid solution. Phospholipids extracted from the precipitated material were subjected to mild alkaline hydrolysis and the water-soluble phosphate esters were separated by two-dimensional paper chromatography[4]. The presence of phosphatidic acid was confirmed by silicic acid chromatography. The phosphatidic acid-containing fraction was then hydrolysed by mild alkali and the resulting phosphate esters separated by ion-exchange chromatography[5]. Specific activities were calculated for each phospholipid and related to the specific activity of the acid-soluble phosphate fraction. All results were related to results from animals fed with 0·75 ml. of a 25 per cent glucose solution, but treated in the same way in all other respects.

The chromatograms showed a phospholipid pattern similar to that seen in liver, but the amount of inositol phospholipid was low. Phosphatidic acid was present in small amounts (approximately 2 per cent of the total lipid phosphorus) but had a higher specific activity than any other lipid; this did not appear to change during fat absorption. The high turnover of phosphatidylinositol in both control and fat-fed animals is noteworthy. The specific activity of the gross phospholipid fraction increased slightly during fat absorption, confirming the studies of Zilversmit *et al.*[2]. This increase appeared to be due chiefly to a more rapid turnover of phosphatidylcholine. The results are summarized in Table 1.

Table 1. RELATIVE SPECIFIC ACTIVITIES* OF RAT MUCOSAL PHOSPHOLIPIDS

Phospholipid	Control rats†	Fat-fed rats†
Phosphatidylcholine	21 (3)	93 (3)
Phosphatidylethanolamine	21 (3)	22 (3)
Phosphatidylserine‡	18 (2)	24 (2)
Phosphatidylinositol	175 (3)	183 (3)
Diphosphatidylglycerol	35 (2)	27 (2)
Phosphatidic acid	429 (3)	442 (3)
Total phospholipid fraction	44 (3)	60 (3)

* Expressed as: $\dfrac{\text{counts per 100 sec per 100 }\mu\text{g lipid P} \times 10^{4}}{\text{counts per 100 sec per 100 }\mu\text{g acid-soluble P}}$

† Average values, number of rats in parentheses.

‡ Since both counts and P content were very low, the difference between control and fat-fed rats is probably not significant.

The increased turnover of phosphatidylcholine during fat absorption may be connected with its requirement in stabilizing chylomicrons. The failure to find an increased specific activity of phosphatidic acid during fat absorption appears to conflict with the results of Johnston and Bearden[3]. There are, however, several important differences in experimental conditions since they studied hamster intestine *in vitro*, absorbing fatty acid rather than partially hydrolysed triglycerides. Phosphatidic acid is an intermediate in triglyceride biosynthesis when L-3-glycerophosphate is the glycerol precursor, but the resynthesis of triglyceride can also take place with monoglyceride as glycerol precursor[6]. This latter pathway, which does not involve phosphatidic acid, could well be more important when triglyceride is fed than when fatty acid is given, since lipolysis would provide monoglyceride.

PHYSIOLOGY

Participation of Hepatic Glucoreceptors in the Control of Intake of Food

IN a previous communication[1], it was shown that anorexia produced by adrenaline is easily conditioned, while anorexia produced by the injection of glucose, instead of becoming conditioned, disappears with repetition. It was also observed during this work that intraperitoneal injection of glucose had a stronger and more persistent anorectic effect than intravenous.

After intraperitoneal injections of glucose (300 mg/kg) the venous and arterial glycaemias started to fall, reaching a minimum of 5–20 mg/100 ml. under the basal 8 min after the injection. Only 5 min after the injection the glycæmia started to rise, reaching a maximum increase of 15–60 mg/100 ml. above the basal, 10–20 min after the injection. On the other hand, anorexia began 1·5 min after the injection, being maximal at the moment of maximal hypoglycæmia, and ended in about 10 min, during the period of maximal hyperglycæmia. Therefore, it seemed that the hypothalamic centres are receiving hypoglycæmic blood during the maximum of the anorexia caused by glucose injection and, on the contrary, they are receiving hyperglycæmic blood just when the anorexia is over. Moreover, in the portal blood, as would be expected, the glycæmia rose immediately after an intraperitoneal injection of glucose, coming to an asymptotic maximum at about 3 min. The basal portal glycæmia was lower than the arterial one; that is, the arterio-portal glucose difference is positive. After an injection of glucose, when arterial glycæmia is decreasing and portal glycæmia increasing, there is a great reduction (or inversion) of the arterio-portal glucose difference, and this coincides with the time of maximal anorexia.

Based on these facts and assumptions, the following hypothesis is propounded:

There should be some 'information' about the difference in arterio-portal glucose, entering the central nervous system, and this could be achieved by a hepatic receptor 'informing' about the intracellular concentration of glucose (or any related metabolite). Therefore, the 'tonicity' of the 'feeding centre' would be the result (at least partially) of a tonic information coming from the liver that will be reduced or suppressed by the increase of glucose intracellular concentration in the hepatic cells. This would explain the stronger effect of adrenaline as compared with that of glucose injection. It will also explain the paradox of hunger in the diabetic, without the assumption that the hypothalamic glucoreceptors need insulin: in the absence of insulin, there will be a great increase on the tonic information from the liver and perhaps also muscle which could not be inhibited in spite of a possible rise on the satiation centre activity.

Further support to this hypothesis comes from the fact that, after glucose has lost its anorectic effect due to repetition, the glycæmic curve does not start any more with a hypoglycæmic phase, but takes a similar time course as the portal curve. Therefore, the arterio-portal difference is preserved all through and no anorexia is produced. Moreover, the hypothesis allows the prediction that small doses of insulin, by increasing intracellular glucose in the hepatic cells, should produce a reduction of food-intake, which was actually observed by Bach[2] and Anand[3].

Increase of Sodium Efflux induced by Epinephrine in the Heart of the Frog

The sinus venosus or the atrium of the frog heart was dissected, cut open, and bathed in Ringer's solution containing sodium-24. When equilibrium had been reached between intracellular and extracellular activity the preparation was mounted in a small chamber through which a rapid stream of inactive Ringer's solution flowed. The activity of the preparation was determined by a scintillation counter in short intervals. After elimination of the extracellular activity the curve which represents the remaining activity consists of two exponential components with time constants of about 10 min and 100 min, respectively[1]. The slow component can directly be determined at the end of a loss curve, and the fast component is evaluated by graphical analysis (Fig. 1). The sum of the two components at zero time is equal to the intracellular sodium content as determined by flame photometry[2]. The flux Φ through the cell membranes is defined by the initial values A_1, A_2 and the time constants τ_1, τ_2 of the two components:

$$\Phi = \varphi_1 + \varphi_2 = A_1/\tau_1 + A_2/\tau_2 \qquad (1)$$

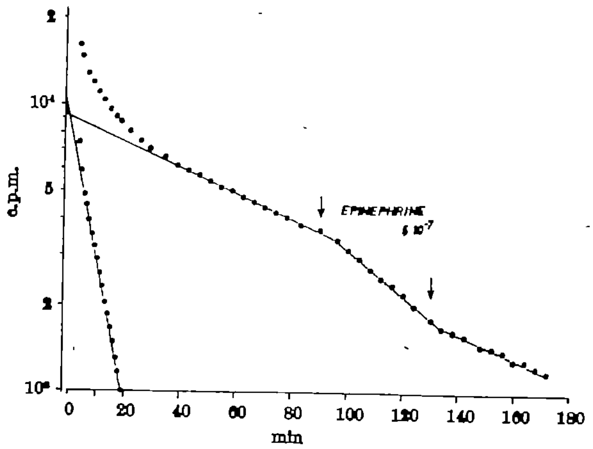

Fig. 1. Effect of epinephrine on the loss of sodium-24 in a frog sinus (open circles). The spontaneous rate was 26 min, but the sinus was driven electrically with 80 stimuli/min throughout the experiment. Temperature, 20° C. Wet weight, 1·1 mg. From min 40 to 90 the loss curve is a straight line (slow component). The fast component is represented by the filled circles. The numerical values of the initial activities and time constants are for the fast component A_1 = 6·2 m.equiv./kg, τ_1 = 9·1 min; corresponding values for the slow component are A_2 = 6·5 m.equiv./kg, τ_2 = 96 min. The fluxes are φ_1 = 0·68, φ_2 = 0·068, Φ = 0·748 m.equiv./kg tissue (wet weight) min. From min 90 to 130 epinephrine causes a decrease of the time constant of the slow component from 96 to 53 min. The slow flux component φ_2 is increased by 82 per cent, the total flux Φ at least by 7·4 per cent. After min 130 epinephrine is omitted, τ_2 increases again to 98 min

The beating rate of the preparation was kept constant throughout the experiment by electrical stimulation at 2–3 times the spontaneous rate of the preparation. Moreover, the effect of changes in frequency on the loss curve was tested and was found to be minimal for the slow component, but an increase in outflow of sodium could clearly be shown for the fast component[3].

When epinephrine was added to the perfusing Ringer's solution (final concentration 5 × 10^{-7} g/ml.) for 10–30 min an increase in the rate of loss of sodium-24 of both sinus and atrial preparations occurred. The time constant of the slow component can increase up to 100 per cent. When epinephrine is omitted the original rate of loss of sodium-24 is re-established (Fig. 1). The effect of epinephrine on the fast component of the loss curve seems to be small; the time constant of the fast component, however, cannot be determined with the same accuracy as that of the slow component. In a few experiments epinephrine caused only a transient increase in the loss of sodium-24 : 10–15 min after application of epinephrine the effects disappeared although the drug was still present. The increase in sodium outflow effected by epinephrine was found to be very much reduced or completely suppressed in presence of 2,4 DNP (1 m.mol/l.) or IAA (m.mol/l.) In test experiments with pericardium or adjacent connective tissue epinephrine did not increase the sodium outflow.

In similar experiments using potassium-42, epinephrine caused a comparatively small increase in the loss of activity for both components of the loss curve of atrial preparations.

Assuming that only the time constant of the slow component is affected by epinephrine according to equation (1) the effect of this drug amounts to an increase of total outflow Φ of sodium-24 by 7–10 per cent in our experiments. It cannot be decided whether an increase in sodium permeability and/or increase in the active transport is the basis of this increase in sodium outflow. The effect might be related to the marked tendency of epinephrine to produce depolarization of the membrane potential as observed in the sinus venosus[3,4]. It seems improbable that changes of the action potential produced by epinephrine are responsible for the increase in sodium outflow, since the beating rate of the preparation does not affect the time constant of the slow component of the loss curve.

Piezoelectric Effect in Bone

THERE is convincing evidence that bone has an orderly morphological and microscopic structure. This evidence is derived mainly from electron microscopy, ordinary histological preparations, and microradiography[1]. Such a structure, consisting essentially of apatite crystals embedded in an organic matrix, might be expected to exhibit piezoelectric properties, as in the case of many other multicrystalline structures.

This has been conclusively demonstrated by Fukada and Yasuda[2], who measured the piezoelectric constants of small specimens of compact bone cut from human and ox femurs. These authors conclude from the observed relationship between polarization and stress that the effect is truly piezoelectric, and they suggest that it results from the slipping of collagen fibres past one another.

We have observed the same stress-induced electrical effect in a number of whole bones from different anatomical sites and species, both in bending and compression modes. The bones were cleaned of soft tissue and periosteum, then placed in an ultrasonic cleaner with detergent and finally dried. Electrodes were painted on the bones with conductive paint (DuPont silver paint No. 4817), leads were attached to these electrodes and connected to a vibrating reed electrometer (Applied Physics Corporation model 31), the output of which was displayed on a chart recorder. To minimize electrical pickup the bone being tested was kept in a shielded box and stressed from the outside. Bones which were stressed by bending, such as human ribs or rabbit femurs, were clamped at one end and bent by applying a force normal to the other end. Shorter bones, such as a human toe phalanx, were stressed by applying known compressive forces lengthwise along the bone axis.

Our results may be illustrated by the following example: the ends of a human toe phalanx were squared off with a saw to permit uniform application of the compressive force. Two silver bands, spaced 12·7 mm apart, were painted completely around the mid-portion of the bone. The d.c. resistance between these electrodes was approximately 10^9 ohms. Sudden application of a static force resulted in a potential difference between the electrodes proportional to the stress and with a decay time of about 0·5 sec; the latter appeared to be characteristic not only of the electrical circuit constants but also of some mechanical property (relaxation phenomenon) of the bone. On releasing the stress the same voltage pulse appeared with opposite polarity. The magnitude of the effect was of the order of 0·3 mV/kg of applied force.

It has long been known that the architectural structure of bones depends to a large extent on the mechanical forces acting on them. The fact that surface charges appear on stressed bone may be the controlling factor in bone formation. The local electric fields resulting from such surface charges might be expected to influence the orientation and deposition of ions or polarizable molecules. As evidence for the effect of electric fields on bone formation, Yasuda *et al.*[3] showed that the development of callus in living bone could be induced by electrical energy. Similarly, Bassett[4] has influenced the direction of bone growth in tissue culture by means of electric fields, as well as by inhomogeneous magnetic fields.

A Possible Mechanism of Neurosecretion: Release of Vasopressin by Depolarization and its Dependence on Calcium

IT is recognized that the various influences, nervous and osmotic, which bring about release of the hormones vasopressin and oxytocin from the neurosecretory terminals in the posterior lobe of the pituitary gland act through the parent cells in the supra-optic and paraventricular nuclei. Such a scheme demands that these cell bodies in the hypothalamus regulate release of hormone from their terminals a considerable distance away and it is simplest to suppose that this regulation is effected by action potentials propagated down the supra-opticohypophysial tract. In this view the cells of the supra-opticohypophysial system possess the characteristic property of neurones—the propagation of action potentials—as well as the characteristic property of endocrine organs—the liberation of hormones into the blood stream[1,2].

The purpose of this communication is to give a preliminary account of experiments indicating that depolarization of the endings of the supra-opticohypophysial tract, such as might be caused by action potentials, is an adequate stimulus for the release of vasopressin and suggesting an explanation of the way in which depolarization may act.

The experiments were performed on rats weighing about 150 g. The infundibular stem was cut and the posterior pituitary glands rapidly removed, halved and suspended *in vitro* in Locke's solution at 37·5° C. Five glands were used in each experiment. At intervals of 20 min the incubation medium was drawn off and replaced with fresh medium of the same or different composition. The pressor activity of the incubates was then assayed against pitressin using the method described by Dekanski[3]. After 20–40 min incubation in Locke's solution the resting output of vasopressin was generally about 20 μU per gland per min. A much higher rate of secretion occurred when the potassium concentration was raised ten-fold (to 56 mM). A typical effect is shown in Fig. 1*a*. This powerful stimulant effect of excess potassium was found to be dependent on the presence of calcium; there was no increase in vasopressin output when excess potassium was given in calcium-free Locke's solution after a period of 40 min incubation with the calcium-free medium (Fig. 1*b*). The inhibitory effect of calcium omission was readily reversible and potassium regularly regained its effectiveness as a stimulus for vasopressin release after calcium had been restored to the incubation medium. Finally, it was found that calcium itself (2 mM) caused a powerful release of vasopressin when added to a preparation exposed to

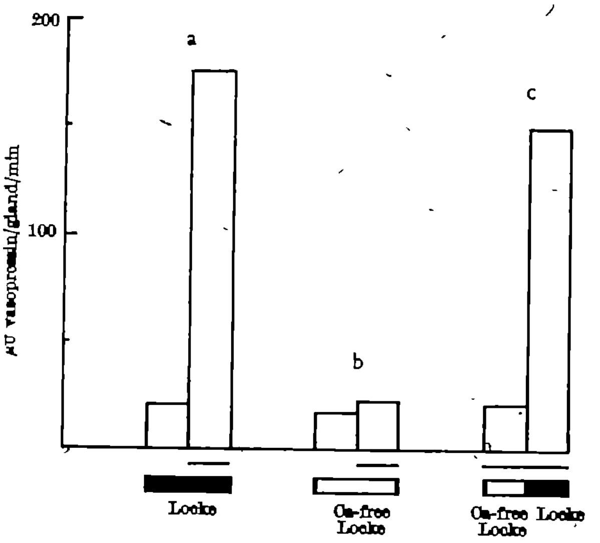

Fig. 1. Vasopressin output from the rat's posterior pituitary gland incubated *in vitro*. Each vertical column indicates the rate of vasopressin release in a 20-min period by a group of five hemisected glands. *a*, shows the stimulant effect of raising potassium from 5·6 to 56 mM; *b*, shows that 56 mM potassium is without effect in calcium-free Locke's solution. Records *a* and *b* are from the same experiment. *b* was obtained first after a total of 40-min incubation in calcium-free medium and *a* was obtained 40 min later after the re-introduction of calcium. *c* shows, in another experiment, the stimulant effect of re-introducing calcium during exposure to 56 mM potassium in a calcium-free medium. The thin horizontal bars indicate the presence of 56 mM potassium. The thick horizontal bars indicate the nature of the basic perfusion medium

calcium-free high-potassium Locke (Fig. 1*c*). The re-introduction of calcium in the absence of excess potassium did not have such a stimulant effect.

Unless the fibres of the neurohypophysis are quite different from peripheral nerves it may be assumed that an extracellular potassium concentration of 56 mM results in a large reduction in membrane potential. For example, in the small nerves of the mammalian vagus which, like those of the pituitary, are non-myelinated, such a concentration of potassium lowers the resting potential to about 1/3 of its normal value[4]. The stimulant effect of excess potassium would therefore suggest that depolarization of the endings of the supra-opticohypophysial tract is an adequate stimulus for vasopressin release. The additional observations on the inhibitory effect of calcium omission and the stimulant effect of adding calcium during exposure to excess potassium indicate that calcium has a key role in the release process. In interpreting these results it would seem most profitable to consider the existing evidence on the role of calcium in the secretory activity of another endocrine gland of neural origin, the adrenal medulla. The medulla, too, is stimulated by excess potassium, and calcium is required for the response[5]; moreover, the addition of calcium during exposure to excess potassium increases the rate of secretion[6]. It is further known that adrenal medullary secretion varies directly with the extracellular calcium concentration over a wide range of concentrations above as well as below the normal[5], that calcium itself is a secretogogue in several different situations known to increase membrane permeability[5,6] and that potassium increases the rate of uptake of calcium-45 by the medulla[7]. The conclusion which has been drawn from these experiments on the adrenal medulla is that calcium acts as a crucial link in the process of 'stimulus-secretion coupling'[5-8]. Although the present observations on the neurohypophysis are comparatively limited, they suggest a similar mechanism of secretion. As a working hypothesis it may therefore be proposed that the release of vasopressin by the neurohypophysis is effected by the arrival of impulses from the supra-optic and paraventricular nuclei which, by depolarizing the endings of the supra-opticohypophysial tract, promote calcium influx (as is known to occur in peripheral nerves[9]) and that the appearance of free calcium ions somewhere in the endings then causes the release of the stored hormone.

A more complex mechanism of release of neurohypophysial hormones has been postulated by Abrahams, Koelle and Smart[10] and Gerschenfeld, Tramezzani and De Robertis[11], who have speculated that acetylcholine may have some physiological role in the release of the hormones from the endings of the supra-opticohypophysial tract. The first group base their conjecture on histochemical evidence that cholinesterase is present in this system, and the second on the finding of 'typical synaptic vesicles' in the endings. In some preliminary experiments with Dr. A. M. Poisner, no release of vasopressin was found when the posterior pituitary was exposed to acetylcholine 10^{-4} g/ml. with or without eserine 10^{-5} g/ml., carbachol 10^{-4} g/ml. or nicotine 10^{-4} g/ml.

When considered along with the existing evidence that calcium is involved in the release of catecholamines from the adrenal medulla[5-8] and of acetylcholine from cholinergic neurones[9,12] the present findings suggest that calcium may have a general role in 'stimulus-secretion coupling' in neurones and endocrine glands of nervous origin.

PHARMACOLOGY

Role of Species Specificity in Failure of Inhibition of Guinea Pig Anaphylactic Sensitization with Cancer Chemotherapy Drugs

Three years ago Schwarz and Dameshek showed that 6-mercaptopurine could block the formation of antibodies to foreign protein in the rabbit[1]. This phenomenon has been verified by some, and its existence questioned by others. To understand better the mechanisms involved in the drug-induced antibody blockade, it is necessary to examine those variables which enhance or prevent this blockade of antibody formation. The work reported here gives evidence that the effect of the cancer chemotherapy agents in blocking primary antibody formation depends, at least in part, on the species studied.

The techniques used have been described in detail elsewhere[1,2]. Briefly, approximately 400-g stock albino guinea pigs were given daily intraperitoneal injections of the test drug according to the following schedule: (1) 6-mercaptopurine, 50 mg/day; (2) vincaleukoblastine, 10 γ/day; (3) actinomycin-*D*, 10 γ/day; and (4) *cyclo*-phosphoramide, 10 mg/day. The drugs were given daily for ten days.

10 mg of purified ovalbumin were given intraperitoneally to the experimental animals on the second day of administration of the drug. Control animals received only ovalbumin. Three weeks after the initial injection of ovalbumin, an intracardiac eliciting injection of 2 mg of ovalbumin was given. Immediate death in anaphylactic shock provided the end point.

The dosage schedule used was determined in preliminary toxicity studies in our laboratory. It is seen from Table 1 that 6-mercaptopurine and *cyclo*phosphoramide were less toxic than the remainder of the drugs studied, even though the former were dosed in 1,000-fold greater quantities.

Table 1

	Total animals	Drug toxicity deaths
6-Mercaptopurine	30	3
Vincaleukoblastine	30	12
Actinomycin-*D*	30	16
*Cyclo*phosphoramide	30	9
Controls	30	0

Table 2

	Animals elicited	Fatal anaphylaxis	Survivors
6-Mercaptopurine	27	25	2
Vincaleukoblastine	18	15	3
Actinomycin-*D*	14	14	0
*Cyclo*phosphoramide	21	1	20
Controls	30	27	3

The anaphylaxis rate in the several groups are summarized in Table 2.

*Cyclo*phosphoramide prevented fatal anaphylaxis in 20 of 21 animals. This verifies our previous work in which we showed that in the guinea pigs the drug prevented development of anaphylaxis[2] and of precipitin formation as measured by the Preer agar diffusion technique[3].

6-mercaptopurine, actinomycin-*D* and vincaleukoblastine were completely ineffective in preventing anaphylaxis; the survival rate with the drugs was not significantly greater than that of the control group which received ovalbumin without drug therapy.

The finding that *cyclo*phosphoramide blocks anaphylaxis in the guinea pig, while 6-mercaptopurine, vincaleukoblastine and actinomycin-*D* do not, we interpret as evidence that species specificity plays a significant part in the action of these drugs. A similar interpretation has been suggested by Genghof and Battisto, who showed no inhibition of precipitin formation in guinea pigs receiving 6-mercaptopurine[4]. Frisch and Davies examined the inhibition of hæmagglutinin formation in mice by purine and pyrimidine analogues and noted great variation in the effectiveness of the drugs tested in this species[5].

It has been stated[1] that immunological unresponsiveness produced by the cancer chemotherapy agents may be due to a general inanition of the animals. Our data would not support this concept; the animals with the greatest weight loss and highest death rate were those receiving vincaleukoblastine and actinomycin-*D*. Neither drug evidenced the ability to inhibit antibody formation.

In summary, *cyclo*phosphoramide blocks the development of anaphylaxis to ovalbumin in the guinea pig. In equally or more toxic doses, 6-mercaptopurine, vincaleukoblastine and actinomycin-*D* do not afford protection. We interpret this as evidence of the species specificity of this class of drugs in inhibiting antibody formation.

Estimation of Methylpentynol

Methylpentynol, a central nervous system depressant, is a tertiary carbinol. Previous methods for its estimation consist of distilling the drug which is volatile out of the tissue or fluid sample into ammoniacal silver nitrate. By virtue of its acetylinic bond methylpentynol combines quantitatively with the silver to form a precipitate. Since two moles of silver react with each acetylinic group[1] the quantity of methylpentynol present can be detected by either colorimetric determination of the amount of silver in the precipitate[2] or by back-titration of the uncombined silver in the supernatant with potassium thiocyanate[3], recovery curves for methylpentynol being obtained by the addition of known quantities of methylpentynol to ammoniacal silver and titration with potassium thiocyanate. The former method is sensitive to 1·0 mg and the latter to 0·1 mg methylpentynol.

Present work on the recovery of the drug from the brains of small animals necessitated the refinement of the technique and a potentiometric method was developed. The specimens containing methylpentynol were heated in a water-bath at 90° C and the volatile drug drawn by an air-stream through 0·0125 M alkaline silver reagent with the formation of an insoluble silver derivative. The excess silver in the supernatant was titrated against 0·0125 M potassium iodide solution. The equivalence point was taken as the centre of steepest portion of the titration curve (Fig. 1), usually between 350 and 400 mV. This was measured with a *p*H meter using a silver electrode (20 s.w.g.) and a reference sodium sulphate glass electrode connected to the solution through a potassium nitrate agar bridge. The end point was plotted graphically so that inaccuracies due to drop size delivered from the 5 ml. burette were not crucial.

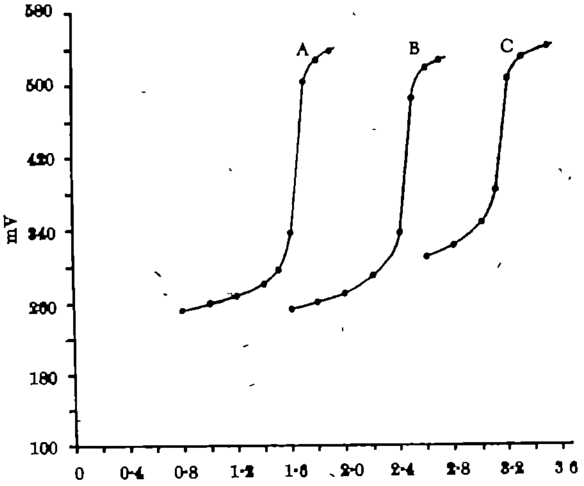

Fig. 1. Titration curves for: *A*, distilled standard of 1·0 mg methylpentynol; *B*, drug sample distilled from cat brain; *C*, control specimen of 0·0125 M ammoniacal silver nitrate

The method enabled 0·01 mg methylpentynol to be detected. Examination of the reliability of the technique revealed that the correlation between the amount of methylpentynol and its estimation varied between 0·92 and 0·96 ($P < 0{\cdot}01$), whereas for the chemical method[3] r varied between 0·64 and 0·93, the former value not being significant. The standard error of the titration of 0·5 mg methylpentynol was 0·012 mg (12 estimations); mean recoveries of 0·5 mg methylpentynol from distilled water were 99, 99 and 102 per cent. Drug recoveries were not affected by the presence of brain tissue ($P > 0{\cdot}1$).

This sensitive and reliable method for the estimation of a central depressant drug made the technique of considerable value in correlating drug concentration in the brain with cerebral function.

Increased Uptake of Mercury in Mouse Brain caused by 2,3-Dimercaptopropanol

2,3-DIMERCAPTOPROPANOL (BAL) is generally used in the treatment of mercury poisoning. In the case of acute mercury poisoning there is evidence to indicate that such treatment is beneficial[1]. Experiments on animals[2,3] have shown that BAL effects a redistribution of the mercury in the body and enhances the urinary excretion of the former, thereby mobilizing mercury accumulated in the kidney, which is the critical organ in acute mercury poisoning. In chronic mercury poisoning, however, the brain is the critical organ, because of the slow elimination of mercury from some of its parts[4]. It was therefore considered important to learn how BAL therapy affects the uptake of mercury by brain tissue. In one approach to this problem mice were given mercury-203 (0·5 mg mercury/kg body-weight), together with BAL in about equivalent amounts (0·4 mg BAL/kg). Controls were given only the mercury compound. The animals were killed at various intervals after the injection. Autoradiograms of whole-body sagittal sections were made as described earlier[5]. The order of isotope concentration in the organs was determined by densitometric comparison with an isotopic standard 'staircase'.

The autoradiograms revealed that the uptake of mercury in the brain was greater when phenyl- or methyl-mercuric compounds were given together with BAL than when they were given alone. Fig. 1 shows the autoradiograms of sagittal sections of mice injected with phenyl-mercuric acetate (upper), and with phenyl-mercuric acetate + BAL (lower). The animals were killed 8 days after the injection. The increased uptake of radiomercury in the brain of the BAL-treated mouse is well illustrated. The standard 'staircase' below each section shows the density caused by decreasing concentrations of the isotope in geometric series (ratio ½). In the case of injection of inorganic mercury compounds the autoradiograms did not provide any conclusive evidence as to how BAL treatment affects uptake in the brain. However, further experiments are being made in this regard. Detailed

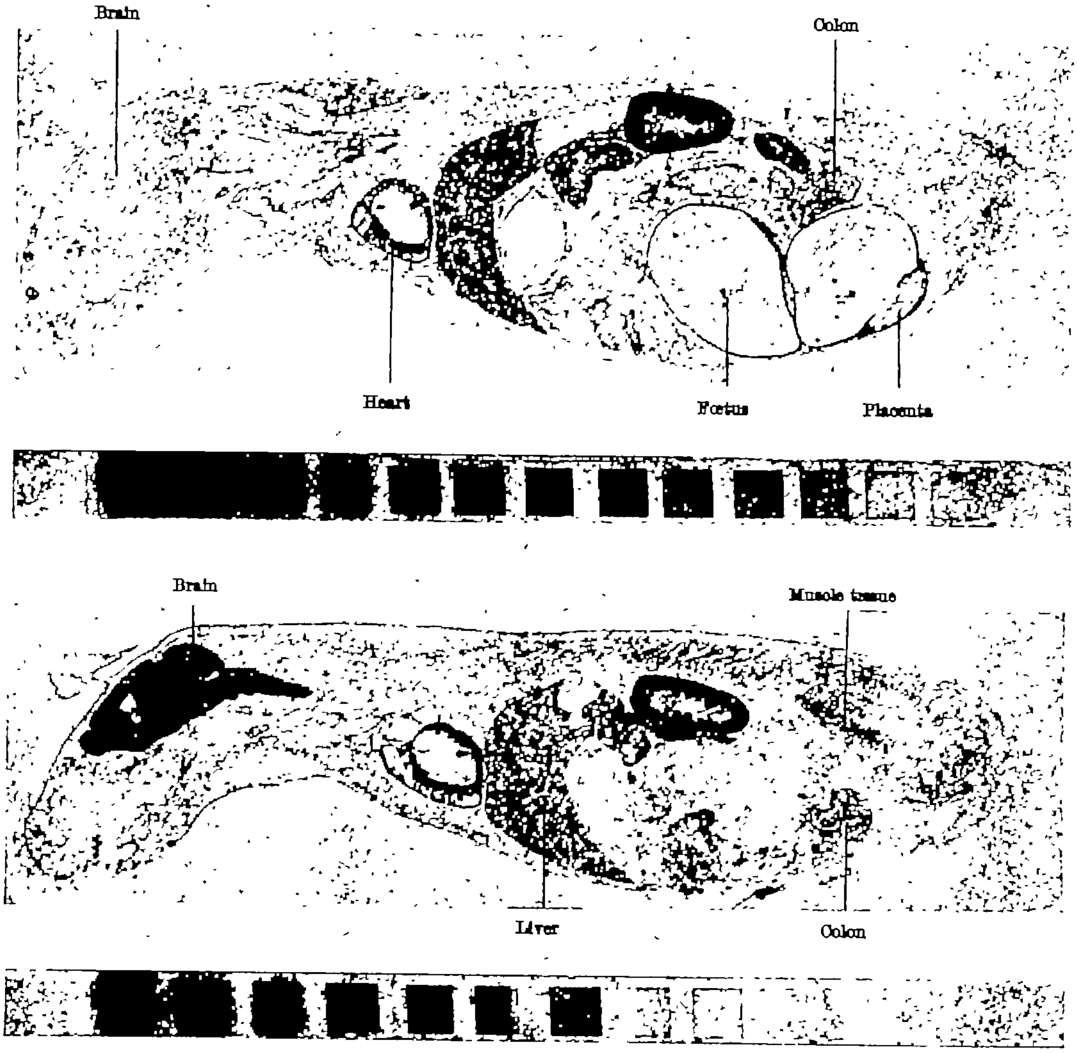

Fig. 1. Autoradiograms of distribution of mercury in whole-body sagittal sections of mice 8 days after injection of phenylmercuric acetate (upper), and of phenylmercuric acetate and BAL (lower). Below each section is the isotope standard 'staircase' autoradiographed on the same film

reports of the studies referred to here will be published elsewhere.

HÆMATOLOGY

Decreased Erythrocyte Survival in Alloxan Diabetic Rat

Although numerous metabolic activities have been investigated in the alloxan diabetic rat, the red cell survival has not been reported. Derangement in the metabolism of the human erythrocyte in diabetes mellitus was shown recently by Long and Carson[1]. The present communication reports a reduction in the red cell life-span in the alloxan diabetic rat.

Albino rats were rendered diabetic by the intravenous injection of 40 mg alloxan/kg body-weight. The diabetic animals (blood sugar-levels more than 300 mg per cent) were tagged with 10 μc chromium-51 three weeks after alloxanization in order to minimize the possibility of a direct effect of alloxan on the erythrocytes. The time in days between tagging and the disappearance of the radioactivity from the blood is taken as the maximal survival time. The details of the procedure have been published elsewhere[2].

Table 1. Maximal Survival Time of Erythrocytes of Normal and Alloxan Diabetic Rats*

	Normal		Alloxan diabetic	
	Body-weight (g)	Max. survival (days)	Body-weight (g)	Max. survival (days)
Mean (± *S.D.*)	206 (± 18)	68 (± 3) $P < 0·01$	146 (± 18)	56 (± 1)

* Nine rats in each group.

Table 1 shows that while normal rats had an average maximal survival time of 68 (±3) days, the alloxan diabetic rats had an average value of 56 (± 1) days. These results indicate clearly that alloxan diabetes reduces significantly the survival of red cells in the rat. Although three weeks were allowed between alloxanization and tagging, one cannot exclude the possibility that the observed effect might be, at least in part, due to the direct action of alloxan on the erythrocytes. However, of 11 diabetic rats, 2 recovered spontaneously after tagging, and their erythrocytes were found to have maximal survival times of 60 and 68 days, values which approach those of the normal animals. This tends to provide evidence against the direct effect of alloxan on the red cells. Moreover, György and Rose[3] showed that although alloxan hæmolyses red cells from vitamin E-deficient rats, it had no such effect on those from normal animals.

This investigation was supported by research grants No. *AM*-4050 and *RG*-6105 from the U.S. Public Health Service, and No. *AT*-(40-1)-2681 from the U.S. Atomic Energy Commission.

PATHOLOGY

Effect of a New Anticancer Agent, 1,4-Dimethyl-1,4-Diphenyl-2-Tetrazene, on a Transplantable Mammary Adenocarcinoma (72*j*) and Spontaneous Mouse Breast Tumours

1,4-Dimethyl-1,4-diphenyl-2-tetrazene[1] (MPT) inhibits the growth of transplanted 72*j* mammary adenocarcinoma carried in C_3H mice. Its activity was found during the screening[2,3] of compounds structurally related to the antineoplastic agent 3,3-dimethyl-1-phenyltriazene[4]. The corresponding 1,4-diethyl[5] and 1,4-di(*p*-nitrophenyl) analogues of MPT were also found active against this tumour. Extensive laboratory evaluation of MPT and synthesis of additional compounds are in progress and will be reported in detail[6,7]. The following biological findings were considered to be of immediate interest.

MPT given subcutaneously or intraperitoneally over a wide range of doses (that is, 2–50 mg/kg/day) prolonged the median survival-time of mice bearing the 72*j* mammary adenocarcinoma to about 60 days, from an average of 30 days in control animals. (Treatment was started 17 days following transplantation. Experimental design in both the transplanted and spontaneous tumour test systems was that introduced by Goldin[8].) In contrast, THIO-TEPA, a known clinically useful anticancer agent, was active over a much narrower range of doses (that is, 0·8–2 mg/kg/day), and had an estimated maximal median survival-time of 50 days. MPT fed in the diet resulted in prolongation of the median survival-time to about 100 days (500, 1,000 or 2,000 mg/kg/day). This median survival-time is the longest observed in these laboratories with any anticancer agent given to the 72*j* mammary adenocarcinoma bearing mouse.

MPT was also interesting because of its apparent ability to prolong significantly the median survival-time of spontaneous tumour-bearing C_3H mice. MPT given subcutaneously (6 or 20 mg/kg/day) to C_3H mice bearing spontaneous mammary tumours increased the maximum median survival-time from 35 days in control mice (starting from the time the mice were placed on test) to 68 days. The compound showed effects over a wide range of doses: that is, 2–150 mg/kg/day. MPT was less effective when given intraperitoneally. By the oral route the median survival-time was prolonged to 70–80 days (500, 1,000 or 2,000 mg/kg/day) versus 37 days for control animals (see Table 1 for results of diet administration).

Table 1. Survival Data of C_3H Mice bearing Spontaneous Mammary Tumours

Compound	Estimated daily dose (mg/kg)	No. of mice/group	No. of exp.	Mean median survival (days)
MPT (in diet)	2,000	5	5	77*
	1,000	5	5	78*
	500	5	5	73*
THIO-TEPA (in drinking water)†	6·7	5	2	42
	4·5	5	2	37
	3·0	5	2	39
	2·0	5	2	43
	1·3	5	2	46
	0·9	5	2	34
Controls (no treatment)	—	5	7	37

* Significant prolongation of median survival $P = 0·01$.
† Solutions were made up fresh daily.

In contrast, THIO-TEPA (by any route of administration) had no effect on the median survival-time of spontaneous tumour-bearing mice.

An earlier report indicated that marked bone marrow destruction was found concomitant with antitumour activity in the laboratory evaluation of alkylating agents and many antifolic compounds[9]. In similar experiments MPT caused no depression of the marrow concomitant with tumour inhibition; moreover, this compound was not identified as an alkylating agent when tested chemically by the Friedman and Boger method[10]. MPT was completely ineffective against the $6C_3HED$ lymphosarcoma and the sarcoma 180 tumour when given by any of the routes or dosage schedules mentioned here.

It should be noted that in none of these reported investigations was destruction of tumour tissue (neither spontaneous nor transplanted 72*j* mammary adenocarcinoma) observed: that is, growth was apparently held in abeyance to size tolerated by the host. Short-term tumour growth investigations (1 week of therapy) did not reveal, as well as did the survival examination cited here, the interesting biological aspects of this compound.

Effects of Corticosteroids on Experimental Amœbiasis

The examination of the influence of drugs on amœbiasis has depended in large part on results obtained from experimentally infected laboratory animals. Conventional methods for the establishment of experimental amœbiasis have involved administration of amoeba *per os* or *per anum*, or the injection of trophozoites into the cæcal lumen.

The most widespread method is that of Jones[1] for the intracæcal inoculation of amœbic trophozoites, which produces multiple, disseminated lesions, of different sizes in different locations, and great diversity in the pathological progress of the experimental disease. The unpredictable degree of infection makes it impossible to standardize lesions so that they will be suitable for critical studies. Similarly, *per os* or *per anum* administration of amoebae is unsuitable for critical evaluation of the complexities in amœbiasis because uniformity of infection cannot be established.

Recently, an intramural inoculation technique has been developed involving the injection of amoebae into the wall of the intestine[2]. Inoculation is made just below the serosa of the cæcum with negligible injury to the tissue at the site of injection and mixing of the injected amoebae with the contents of the cæcal lumen is avoided. The most important advantage of the intramural technique is that it provides a single-lesion infection, standardized in its nature, characteristics and development, always located at the spot of inoculation, from which the pathological process proceeds toward the mucosa. In about one week, a typical amoebic abscess forms, and there is active migration of amoebae towards the mucous membrane, and also through the physically intact mucous membrane into the lumen of the cæcum.

Some time between the fifth and tenth days, the abscess perforates through the mucous membrane and the lesion is converted to a typical amœbic ulcer with central erosion, deep necrosis and a widely undermined mucosal margin. The mass of the amoebae are now spilled into the intestinal lumen and marks the end of the period of existence of the experimental model since multiple, secondary lesions can now develop.

This communication is concerned with the influence of corticosteroids on the rate of pathological development in the early, single-lesion phase of the disease. The decision to test corticosteroids in this model disease was based on: (1) the general knowledge that infectious disease is often a contraindication for therapy with corticotropin or cortisones; (2) the fact that there are clinical reports which attribute the exacerbation of latent amœbiasis to the use of cortisone[3,4].

The dose of corticosteroid used in this work was 25 mg/kg. In the first and second experiments the drug was given *per os* the day before infection, repeated on the day of infection and for three consecutive days after infection. In the third experiment, hydrocortisone was given by intraperitoneal injection the day before infection and every other day thereafter. In the fourth experiment, hydrocortisone was given as in the first two, but medication was continued until the time the animal died or was killed. Controls were handled in the same manner as treated animals, and were given equivalent volumes of vehicle.

The infection was initiated as already described. Male guinea pigs weighing about 250 g were placed under hexobarbital anæsthesia and inoculated subserosally in the cæcal wall with approximately 10,000 trophozoites of a virulent strain of *Entamoeba histolytica* which had recently been isolated from an active clinical human case.

Evaluation of the pathological process was based on observations of all animals with single lesions.

The extent of the hyperæmic zone surrounding the lesion was scored on the following basis: 0, no inflammation; 1, slight hyperæmia; 2, moderate hyperæmia; 3, pronounced hyperæmia. Direct smears of the mucosa in the vicinity of the lesion were made at the time the cæcum was excised and opened, and examined microscopically for the prevalence of amoebae. The scoring system for microscopic index of abundance of amoebae was as follows: 0, none present; 0·5, less than 1 per field; 1, 1–5 per field; 2, 6–30 per field; 3, 30 or more per field. A minimum of 20 fields was examined with the 10 × objective and a 10 × eyepiece.

In the first experiment, cortisone and hydrocortisone treatment were compared, and results are shown in the upper part of Table 1. On the basis of objective measurement, it is seen that in this series the lesions were larger in corticosteroid-treated animals than in untreated controls. When cortisone-treated and hydrocortisone-treated animals are considered together, their mean combined lesion size is 12·79 ± 1·44 mm^2, with $P < 0{\cdot}02$ for significance of difference from control value. Perforations were more frequent in corticosteroid-treated animals. Prevalence of amoebae in the intestinal lumen was most marked in animals which had been given hydrocortisone.

Table 1. Some Influences of Corticosteroids on Experimental Single-Lesion Amœbiasis in the Guinea Pig

Treatment	No. infected	No. surviving on fifth day with single lesions	Microscopic index (No. of amoebae)	Hyperæmic index	Lesion area (mm^2 ± *S.E.*)	Perforation
Control	5	4	0·75	1·75	7·17 ± 0·97	2/4
Hydrocortisone acetate	4	3	1·33	1·67	12·96 ± 3·34 $P > 0{\cdot}1$	2/3
Cortisone acetate	4	4	0·33	1·50	12·06 ± 1·28 $P < 0{\cdot}02$	4/4
Control	6	6	0·50	2·17	24·32 ± 4·47	3/6
Hydrocortisone acetate	6	6	0·67	3·00	26·17 ± 3·20 not. sig.	2/6

Subjectively, from the appearance of the animals, it was felt that both drugs were having an adverse effect on host resistance, and the work was extended with hydrocortisone. Repeating the initial experiment with hydrocortisone alone gave results which are shown in the lower part of Table 1. Once again the prevalence of amoebae in the intestinal lumen was greater in the hydrocortisone-treated animals than in controls, and surrounding tissue reactions were more marked. All treated animals showed a highly hyperæmic response.

In a third experiment, 14 guinea pigs were given a light amœbic infection by intracæcal inoculation. Half were given hydrocortisone every other day, and all survivors were killed and autopsied on the 11th day after infection. The gross appearance of hydrocortisone-treated animals was far worse than that of controls. Treated animals invariably showed massive hæmorrhagic and hyperæmic involvement of the entire cæca while control animals showed only occasional scattered hyperæmic patches.

A final experiment was carried out with guinea pigs which had received an intramural inoculation of slightly more than 13,000 amoebae each. Half the animals received hydrocortisone daily. The majority of the animals in both treated and control groups were killed on the fifth day after infection. Again, hydrocortisone-treated animals showed hyperæmia, hæmorrhage and occasional metastasis of amœbic foci while such findings were rarely found in control animals, and then only to a minor degree. Four treated and four control animals were not killed on the fifth day, but were maintained with the intention of killing them on the tenth day after infection. By the tenth day, three of the four hydrocortisone-treated animals had died spontaneously, while none of the controls had died. Since guinea pigs have a life expectancy of about twenty days after an infection of this magnitude, we attribute these early deaths to the influence of the corticosteroid on the progress of the disease. At autopsy, these animals evidenced a fulminating amœbiasis characteristic of animals dying on or about the twentieth day without treatment.

Thus, we have found that administration of corticosteroids results in marked exacerbation of pathology in animals with amœbic disease. The mode of action for these changes is not yet clear. Our results so far suggest several lines of future investigation. These include the response of the experimental disease to decreased dosages of corticosteroids, and the use of axenic cultures of *Entamoeba histolytica*[5], not available at the time this work was done.

Azo Dye Liver Carcinogenesis: Reaction of Hydroxymethylaminoazobenzene with Nucleic Acids *in vitro*

IN a long series of aminoazobenzene derivatives tested for hepatocarcinogenicity in the rat only those compounds with at least one *N*-methyl group are markedly active[1]. The hypothesis has been advanced that the actual carcinogen is a derivative of the parent dye and that its production may be hindered or enhanced under different dietary conditions, or in different species. The *N*-methyl group is thought to undergo stepwise oxidation in the liver to formaldehyde, the first product being an *N*-methylol derivative, hydroxymethylaminoazobenzene (I) in the case of methylaminoazobenzene[2]. Such compounds are reactive species and are capable of alkylating thiol groups, amino-groups, phenolic residues and so on by a Mannich condensation. It has been suggested that reactions of this type account to some extent for the formation of protein-bound dye *in vivo* in the case of dimethylaminoazobenzene (butter yellow) and certain of its derivatives[1,3,4]. In view of the importance of DNA and RNA in cellular metabolism, an investigation has been carried out to determine whether such methylol derivatives are capable of reacting with nucleic acids *in vitro*.

It is not possible to isolate the *N*-methylol derivative of aminoazobenzene, but at neutrality it will exist in equilibrium with aminoazobenzene and formaldehyde when the latter reactants are mixed at room temperature.

(I)

In the absence of any competing reactant, it condensed rapidly with aminoazobenzene forming di-(4-phenylazophenylamino) methane (II):

$$\text{PhN} = \text{NC}_6\text{H}_4\text{NHCH}_2\text{OH} + \text{PhN} = \text{NC}_6\text{H}_4\text{NH}_2$$
$$\rightarrow \text{PhN} = \text{NC}_6\text{H}_4\text{NHCH}_2\text{NHC}_6\text{H}_4\text{N} = \text{NPh} \quad \text{(II)}$$

but condensation readily occurred with RNA when this was added to the equilibrium mixture.

Yeast RNA (200 mg) in water (10 ml.) was treated with a mixture of 40 per cent formaldehyde (0·1 ml.) and aminoazobenzene (150 mg), and the mixture shaken for 10 min. After standing overnight at room temperature the mixture was extracted many times with ether or benzene until no further colour could be removed from the yellow aqueous solution. RNA, which was coloured yellow, was precipitated with ethanol after adding sodium acetate to a concentration of 2 per cent. Repeated washing of the RNA with ether and benzene failed to remove further colour. The amount of dye bound was 0·0045 mg/mg RNA. In the absence of formaldehyde no dye binding occurred either with aminoazobenzene or the cross-linked compound (II) which was formed to some extent during the reaction.

A second run using RNA (300 mg), aminoazobenzene (150 mg), 40 per cent formaldehyde (0·05 ml.), water (60 ml.) and ethanol (40 ml.) gave a similar product after 10 min at room temperature (0·001 mg dye/mg RNA).

The nature of the dye binding to RNA has not yet been fully investigated but a Mannich condensation involving base amino-groups seems likely. The dye–RNA complex has the properties one would expect from a compound possessing an —NH.CH$_2$.NH— linkage, since it is stable to alkali (0·3 N caustic soda for 12 h at room temperature), but decomposes rapidly in the presence of 6 N hydrochloric acid. After neutralization of the acid solution with ammonia the dye was extractable into benzene, showing that it was no longer bound to RNA. The extracted dye had major absorption peaks at 380 mμ in neutral solution and at 500 mμ in 6 N hydrochloric acid, indicating that it was probably aminoazobenzene. In aqueous solution the RNA–dye complex slowly dissociated and with one sample of the complex, containing 0·0014 mg dye/mg RNA–dye complex at a concentration of 20 mg complex/ml., equilibrium was reached within 2 h.

Further evidence that a covalent bond was formed between the dye and RNA rather than simple adsorption of the dye on to the RNA was obtained by hydrolysing the RNA to its nucleotides with 0·3 N caustic soda for 12 h, when it was still not possible to extract the dye with benzene.

In the case of DNA the situation was complicated by the adsorption of large quantities of free dye, both aminoazobenzene and II, although this could be removed from the more rigidly bound dye by extraction of an alkaline solution of the complex with benzene or ether.

Salmon sperm DNA (40 mg) in water (10 ml.) was treated with formaldehyde (0·05 ml.) and aminoazobenzene (95 mg) and the mixture left at room temperature for 11 h. The mixture was extracted three times with ether, and the DNA–dye complex was then precipitated with ethanol. The yellow DNA was washed many times with ethanol and then with benzene, the final washing being only slightly coloured. It was then dissolved in water and reprecipitated with ethanol. The DNA–dye complex in 6 N hydrochloric acid had an absorption maximum at 500 mμ corresponding to 0·04 mg dye/mg DNA–dye complex.

7 mg of DNA–dye complex in water (20 ml.) were treated with concentrated ammonia (0·15 ml.) and extracted with benzene until no more colour could be removed. The nearly colourless alkaline solution when treated with an equal volume of concentrated hydrochloric acid had an absorption maximum at 500 mμ corresponding to 0·02 mg dye/mg DNA. Treatment of the complex with 6 N hydrochloric acid followed by neutralization and extraction with benzene removed this remaining dye. These experiments suggest that half the dye associated with DNA when first estimated was only loosely bound, whereas the remainder was associated in a manner comparable to that found for RNA in that it was stable to alkali but decomposed in acid solution.

In a second run, DNA (50 mg) in water (50 ml.) was treated with aminoazobenzene (150 mg) in ethanol (40 ml.) and formaldehyde 0·05 ml. After 2 min the yellow fibrous DNA was precipitated with ethanol after adding sodium acetate to a concentration of 2 per cent. The solid was washed many times with ethanol and reprecipitated twice more from aqueous solution, the solid being washed each time. DNA–dye complex isolated under these conditions contained 0·0027 mg aminoazobenzene/mg DNA–dye complex.

The lability of the nucleic acid–dye complexes in aqueous and in acid media will obviously make isolation from whole rat liver difficult, and may account for the failure to find evidence of extensive binding to nucleic acids with methylated *p*-aminoazobenzene dyes *in vivo*[4,5]. Tritiated butter yellow of high specific radioactivity has been prepared and this is being used to investigate the situation *in vivo* with these facts in mind.

These findings suggest an additional way in which methylated aminoazo dyes might interfere with cellular function in the rat liver. The conversion of an *N*-methyl group to a reactive *N*-methylol derivate *in vivo* raises the possibility that other *N*-methylated carcinogens such as dimethylaminostilbene might also be converted enzymatically into alkylating agents. In this connexion it is of interest that reactions of the alkylating type have been previously implicated in liver carcinogenesis. For example, dimethylnitrosamine, which undergoes metabolic modification in the liver, has been shown to methylate nucleic acids and proteins[6], while certain pyrrazolizidine alkaloids which are liver carcinogens and cause other cellular abnormalities, have recently been shown to be alkylating agents[7].

Failure to protect Mice against Endotoxin with Snake Venom

WHEN bacterial exotoxin, endotoxin, or snake venom is injected intravenously into animals, peripheral vascular collapse occurs. Preliminary investigations demonstrated that the administration of sub-lethal doses of *Escherichia coli*, *Salmonella typhi* or brucella endotoxins protected mice against lethal doses of snake venoms (*Crotalus terrificus* and *Bothrops jararaca*). Since North and Doery[1] have reported that the venom of the Australian tiger snake (*Notechis scutatus scutatus*) protected mice against staphylococcal exotoxin, comparable work was carried out in our laboratory to determine if rattlesnake venom (*Bothrops jararaca*) would protect Swiss–Webster white mice against *E. coli* endotoxin, as well as staphylococcal toxin.

Three methods were used in injecting the materials intravenously into the tail vein in a total volume of 0·5 ml.

Method 1. A needle was inserted into a vein, the venom injected, and then immediately afterwards, with the needle still in place, exotoxin or endotoxin contained in a second syringe was injected.

Method 2. Venom was injected 30 min before either the exotoxin or endotoxin.

Method 3. The venom and staphylococcal toxin or endotoxin were thoroughly mixed at room temperature and then injected. The amounts of venom, toxin or endotoxin remained the same in the mixtures, but were contained in one-half the volume.

Table 1. RESULTS IN MICE RECEIVING LETHAL DOSE OF STAPHYLOCOCCAL TOXIN OR *E. coli* ENDOTOXIN WHEN (*A*) SNAKE VENOM (*Bothrops jararaca*) AND TOXIN OR ENDOTOXIN WERE INJECTED SIMULTANEOUSLY, (*B*) VENOM WAS INJECTED 30 MIN BEFORE THE TOXIN OR ENDOTOXIN

Materials injected	Survivors after 24 h
5 μg venom	0/20
1 : 10 toxin	5/20
5 μg venom followed immediately by 1 : 5 toxin	2/20
5 μg venom followed in 30 min by 1 : 5 toxin	16/20
Endotoxin	2/10
5 μg venom followed immediately by endotoxin	3/10
5 μg venom followed in 30 min by endotoxin	0/10

Table 2. RESULTS IN MICE WITH LETHAL DOSE OF STAPHYLOCOCCAL TOXIN OR *E. coli* ENDOTOXIN WHEN MIXED WITH SNAKE VENOM (*Bothrops jararaca*) PRIOR TO INJECTION

Materials injected	Survivors after 24 h
5 μg venom	0/20
1 : 10 toxin	1/10
Endotoxin	2/10
5 μg venom + toxin	9/10
5 μg venom + endotoxin	1/10

The results presented in Table 1 show that snake venom did not protect against staphylococcal toxin or endotoxin when the two were injected simultaneously. Venom did protect against staphylococcal toxin when the latter was injected 30 min after the venom; but in similar circumstances venom did not protect against endotoxin. Table 2 shows that a pre-injection mixture of venom and toxins protects against a lethal dose of toxin, but no protection against endotoxin resulted from this procedure.

These results confirm the findings of North and Doery[1] that venom will protect mice against staphylococcal toxin. However, such protection is not afforded against endotoxin. Others[2] have shown that pre-treatment of rabbits with venoms accelerates death due to endotoxin. Although exotoxin and endotoxin both induce peripheral vascular collapse, the initial mode of action of each is different. Staphylococcal exotoxin acts directly on the vascular endothelium, whereas the action of endotoxin is mediated through a labile serum factor resulting in the liberation of vasoactive substances[3,4]. Doery and North[5] have suggested that a mechanism whereby venoms inactivate exotoxin involves phosphatidase *A*, an enzyme present in venom, which interacts with phosphatide at the cell surface liberating fatty acid and lysophosphatide. In further observations they have inactivated staphylococcal toxin with unsaturated fatty acids. Preliminary *in vivo* studies in our laboratory with several bacterial exotoxins and with endotoxin have shown that unsaturated fatty acids protect against exotoxins but not against endotoxin.

RADIOBIOLOGY

A Combined Microphoresis–Autoradiography Technique

BASE ratios can be determined with microelectrophoresis (microphoresis) in as little as 5×10^{-10} g RNA[1], a sensitivity which permits intracellular analysis in suitable material. It would be of interest for turn-over studies to evaluate radioactivity in the separated RNA components. Autoradiography is the simplest tool for this purpose, both because of its sensitivity and high resolution.

Tests were performed with graded applications of tracer on microphoresis fibres and with separations of yeast RNA hydrolysate mixed with tracer. These indicated that autoradiograms of individual bands could be resolved and that the fibre did not interfere with the performance of the emulsion.

A biological test was conducted on middle-late larvæ of a local chironomid in Gothenburg, probably *Chironomus thummi*. Whole salivary glands were dissected and cultured *in vitro* in medium '199' (Glaxo Laboratories)[2], containing 11·4 μc. (8-^{14}C) adenosine-5′-triphosphate per ml. (The disodium nucleotide from Schwarz Bioresearch, New York, was 77 per cent pure by ultra-violet analysis, and was used at 5 mM.) The glands were cultured at room temperature for 6 h, during which time they remained viable as judged by the extrusion of abundant secretion. They were fixed for 1 h in Carnoy (chloroform/ethanol/glacial acetic acid 6 : 3 : 1, by volume), a procedure which involves no measurable loss of RNA[3], and then embedded in paraffin and sectioned at 25μ. Individual nucleoli from sections hydrated with 0·01 N acetic acid were isolated intact in an oil chamber using a de Fonbrunes's micromanipulator fitted with two glass needles. RNA was extracted with a buffered ribonuclease solution and hydrolysed in a micropipette as previously described[1]. Aliquots of the hydrolysates corresponding to 6–8 nucleoli were subjected to microphoresis and the amount of bases measured photometrically. (Although base ratios can be determined accurately, absolute amounts can only be determined with an estimated error of about ±25 per cent.) For autoradiography the fibres were taken off the quartz glass on which they had been photographed in ultra-violet light of 257 mμ, and placed on a glass slide which was then exposed to an atmosphere of ammonia for three minutes. Immediately thereafter the slide with the fibre was pressed on to dried Kodak *AR*.10, previously coated emulsion-up on subbed slides. Autoradiograms were obtained of the separations and grains counted at the centre to calculate (in first approximation) a relative electron flux. The results are given in Table 1.

All the detectable radioactivity corresponded with a single band, that is, adenine, except in preparation 2 where also traces were in guanine. For evaluation of autoradiography it should be considered, first, that a compressible fibre of 25–30μ diameter is the actual source and, second, that the label in it remains during exposure in a free-diffusion system, that is, the microphoresis buffer. Allowing for electron scattering, the length of the bulk of the autoradiograms in preparations 3 and 4 compares well with the length of the initial adenine bands (columns *a* and *b*, Table 1). This suggests that appreciable diffusion was prevented by an increased viscosity at 4° C of the buffer; that there is some diffusion is shown by the tailing-off of the autoradiograms (not included in the estimates). A greater compression could largely explain the less favourably comparable lengths in preparations 1 and 2, since the lower temperature of exposure would have further increased the viscosity (preparation 1 showed an autoradiogram excessively broad as well as long). Excluding preparation 1, the specific activity of which would be the most decreased for the previous reasons, the specific activities of preparations 2–4 (column *f*) are in reasonable agreement (for comparison with the other preparations, the differences indicated in footnote 2 for preparation 4 roughly cancel each other). The reproducibility of the determinations is satisfactory within a single fibre, that is, in preparations 2 and 4.

From the present tests the technique would seem useful in the examination of turn-over of RNA components in individually isolated cell constituents. The present needs were to obtain a high labelling of RNA and to apply microphoresis on larger aliquots of this than necessary; that is, the RNA of about two of these nucleoli. It is considered that substantially less radioactivity (as encountered in turn-over work) can be measured, since short exposure times were used and these still resulted in grain densities far above the lower limit for grain counting. Thus, the technique can be coupled with direct autoradiography of nucleoli to encompass the topography of turnover. Improvement in the quantitative aspects can be expected from including known reference amounts of tracer in the microphoretic separations. A single fibre can accommodate 6–7 separations from different cell constituents.

Table 1. MICROPHORESIS–AUTORADIOGRAPHY OF NUCLEOLAR RNA ADENINE

Preparation	Autoradiograph exposed at (°C)	Length of adenine band by ultra-violet light before autoradiography (μ)	Estimated length of autoradiogram (μ)	Adenine by ultra-violet photometry* (μμg)	Net grain count per unit area in autoradiogram of adenine†		Relative specific activity $\frac{(d) \text{ or } (e) \times 100}{(c)}$
		(*a*)	(*b*)	(*c*)	(*d*)	(*e*)	(*f*)
1	−20	180	475	124		44·2	36
2*a* 2*b*		180 225	295 323	150 153 151·5		122·9 134·1 128·5	85
3	4	235	285	155		96·3	62
4*c* 4*d*		215 215	228 228	100 118 109	76·0 76·0 76·0		70

* Average molar ratio of adenine was 34·9 per cent of the sum.

† Exposure and development times of autoradiographs : (*d*) 4·8 days, 30 min. ; (*e*) 6 days, 15 min. The developer was commercial Kodak *D*–19 at 18° C.

Restoration of X-irradiated *L*-cells by Means of Highly Polymerized Isologous Deoxyribonucleic Acid

L-CELLS were treated with sub-cellular fractions after X-irradiation and an appreciable restorative effect was noted after addition of nuclear fraction and to a lesser extent with mitochondria. The results will be presented elsewhere. However, the results of these experiments varied from experiment to experiment. In some experiments significant restorative effect was noticed but in the other additions unirradiated nuclei had no effect.

In order to establish the nature of the restorative agent as well as the cause of variability of our results we have made several analyses. First of all, the effect of isologous macromolecules such as deoxyribonucleic acid have been examined, because some evidence concerning the restorative effect of nucleic acids was reported by others[1-4].

In most experiments a clear restorative effect was noticed after addition of highly polymerized isologous DNA to irradiated culture of *L*-cells under our conditions. This effect also varied from experiment to experiment.

For each experiment 40 Carrel flasks were inoculated with *L*-cells in Eagle's growth medium[5] supplemented with 20 per cent calf serum and 0·8 mg/l. cholesterol. After 14 h of incubation at 37° C, 20 flasks were irradiated with 500 r.; 20 flasks were kept as control. To 5 irradiated flasks DNA was added in final concentration of 35 μg DNA per ml., and to 5 other flasks DNA was added 3 μg per ml. of medium only. With non-irradiated control flasks the same treatment was applied: to 5 control flasks 35 μg DNA/l. was added, and to another 5 flasks 3 μg DNA/ml. After two weeks of incubation at 37° C, colony count was made.

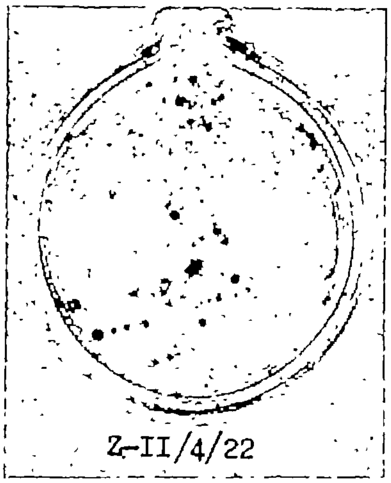

Fig. 1. Colonies of *L*-cells in a Carrel flask. Each flask was plated with 2,000 cells and irradiated with 500 r.

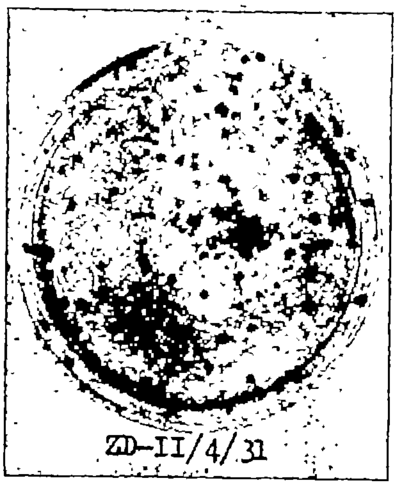

Fig. 2. Colonies of *L*-cells in a Carrel flask plated with 2,000 cells irradiated with 500 r. and treated with 35 μg DNA/ml. medium

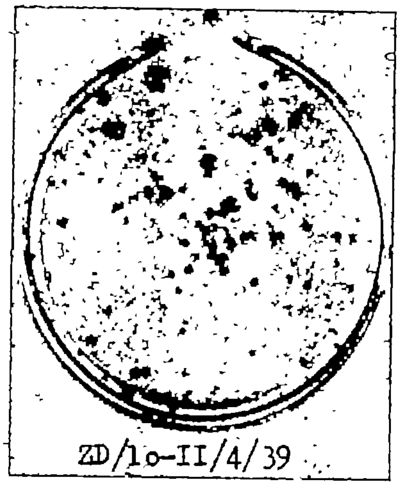

Fig. 3. Colonies of *L*-cells in a Carrel flask plated with 2,000 cells, irradiated with 500 r. and treated with 3 μg DNA/ml. medium

DNA isolation was carried out with a phenol method out of 10^{9}–10^{10} *L*-cells. Such isolated DNA was contaminated with appreciable amounts of RNA (16 per cent) and proteins (6·1 per cent).

Survival for 500 r. under our experimental conditions was 8·8 ± 0·6 per cent. Addition of 35 μg per ml DNA to the irradiated cells increased survival up to 14·8 per cent with respect to the unirradiated control treated with the same amount of DNA. When 3 μg/ml. of DNA was added after irradiation, survival was increased to 13·6 per cent. In unirradiated flasks, plating efficiency was increased by addition of 35 μg/ml. DNA from 56 to 65 per cent. After addition of 3 μg/ml. of DNA, plating efficiency was increased up to 66 per cent. Only colonies with more than 50 cells were counted.

It is evident from these results that addition of isologous highly polymerized DNA leads to restoration of irradiated cells. It is interesting to note that the degree of restoration is the same whether 3 μg DNA/ml. or almost 12 times more DNA was added.

In Figs. 1, 2 and 3 colonies formed from irradiated cells are shown, to be compared with samples treated with DNA.

In some experiments with the same DNA kept in a freezer, results varied to a greater extent.

On the basis of preliminary experiments undertaken to analyse the survival curves of DNA treated and non-treated cells, it seems likely that restoration is connected with an increase of the extrapolation number.

Experiments with denaturated, hydrolysed and heterologous DNA and with purified DNA are in progress.

Maximum Protection of Mice against 8-MeV Electron Irradiation

Mice can be protected from the effects of whole-body irradiation by a variety of different ways. Sulphydryl compounds given immediately before[1,2], hypoxia induced during[3], or infusion of syngeneic bone marrow given after[4] irradiation all afford major degrees of protection. If each of these agents acted by an independent mechanism, then the $LD_{50/30}$ days dose might be expected to be increased by as much as six to eight fold when all were used together. We now report the results of combining these factors.

Male and female inbred *C3H* mice, 15 weeks old, were irradiated with 8-MeV electrons at a dose rate of 40,000 rads/min. All the mice were anaesthetized with 65 mg/kg 'Nembutal' (Abbott) 30 min before irradiation. The protective measures used were: intraperitoneal cysteamine 200 mg/kg 15 min before irradiation; hypoxia, produced by breathing pure nitrogen for 45 sec (the irradiation being given during the last 5 sec of the nitrogen administration); and intravenous injection of bone marrow cells taken from littermates of the same sex 20 h after irradiation. Antibiotics ('Crystamycin', Glaxo) were injected daily for 30 days—50,000 I.U. sodium penicillin *G* and 50 mg streptomycin per kg mouse body-weight.

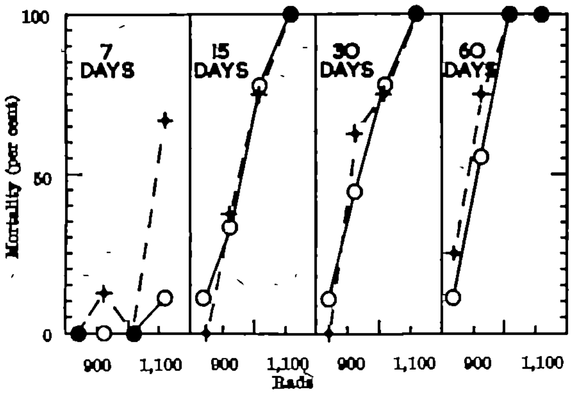

Fig. 1. Percentage mortality of irradiated *C3H* mice at different time intervals after irradiation. The dose received by the protected mice (black crosses) has been divided by 3·8 to compare with the dose received by the unprotected mice (open circles)

The results are shown in the Figs 1 and 2. It is seen (Fig. 1) that a dose reduction factor of approximately 3·8 is observed over a wide range of mortalities when measured at 15, 30 and 60 days after irradiation. From Fig. 2 the $LD_{50/30}$ for the unprotected animals is seen to be 940 rads, while that for the protected animals is 3,520 rads. To compare these figures with equivalent doses of 250-kVp X-rays we have used a relative biological effectiveness of 0·82 for the 8-MeV electrons. This is reasonable when the polarization correction is included[5,6]. The $LD_{50/30}$ unprotected becomes 770-rads X-rays, and the $LD_{50/30}$ protected becomes 2,890-rads X-rays. We believe this latter dose to be the highest $LD_{50/30}$ that has ever been recorded, and it is probably very nearly the highest dose that is possible with present methods of protection. (Burnett and Doherty[7] reported that some survivors had been obtained in mice given up to 2,600 r. γ-radiation when aminoethylisothiouronium bromide hydrobromide protection was followed by treatment with bone marrow and streptomycin. This might be equivalent to about 2,130 r. 250-kVp X-rays[8].) Although the degree of protection achieved here is very large, it falls far short of the product of each factor multiplied together. These results will be published more fully elsewhere.

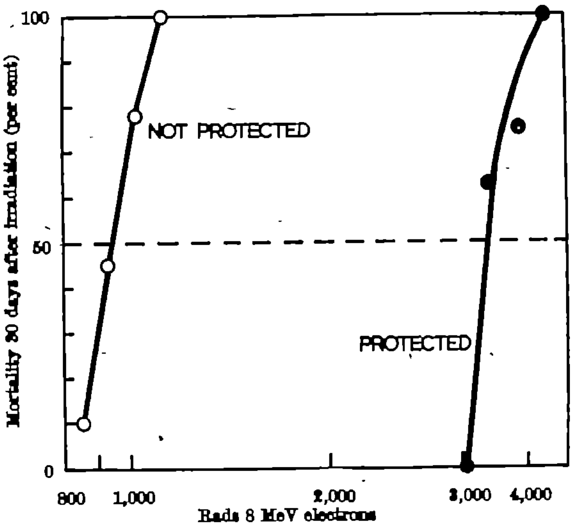

Fig. 2. Percentage mortality of protected and unprotected *C3H* mice at 30 days after irradiation. Dose of radiation on log scale

BIOLOGY

Effect of Air Drying and Dressings on the Surface of a Wound

It has been pointed out that the normal dry scab on a wound exposed to the air includes a superficial part of the dermis, and it was suggested that this is because the exposed dermal tissue is dehydrated[1]. Epidermis migrates below the dehydrated fibrous tissue where there is sufficient moisture for the cells to live. If the surface of the wound is deliberately kept moist by covering the wound with an occlusive film, the epidermis will migrate over the surface of the dermis. In this latter event migration of the epidermis is twice as rapid as when it is forced to pass through the fibrous tissue.

The opposite effect has now been demonstrated, namely, that if a wound surface is artificially dried more extensively than by mere exposure to the atmosphere, then more of the dermis is incorporated in the scab.

For these experiments superficial wounds were made in the skin of the backs of two female Large White pigs. Rapid drying of the wounds was achieved by floating the pigs on a cushion of air on the 'levitation' apparatus described by Scales[2]. In the first experiment, the air temperature was 20° C (pressure, 25 cm water; flow-rate, 1,250 ft.³/min; blowing time, 1 h). In the second experiment, the air was heated to 40° C (pressure, 29 cm water; flow-rate, 1,350 ft.³/min; blowing time, 1 h). After the fresh wounds had been blown on and dried, the pigs were returned to their pens wearing a cage to protect the wounds from damage. Biopsy specimens were taken after three days.

Histologically, it was found that the tissue in the floor of the wound had been affected to a greater depth than normal. Within the affected layer the fibrous bundles were closely packed and there appeared to be no living cells. Epidermis was migrating through the dermal fibrous tissue below the altered layer. The scab therefore was similar to that which forms on a wound exposed to the air, but thicker, incorporating more of the superficial dermal tissue.

Epithelization was measured from serial sections. In the first experiment, in which the wounds were dried by air at room temperature, 34 per cent of the wound area had been re-populated by new epidermis at three days (Table 1). Where warmed air was used to dry the wounds, only 18 per cent of the wound surface was covered by new epidermis at three days (Table 2).

Table 1. EPITHELIZATION AFTER AIR BLOWING

Time	Wound	Total length of epidermis (mm × 10^{-3})	Total length of section examined (mm × 10^{-3})	Percentage of epidermis
3 days	5	17,428	55,012	32
	6	20,687	66,511	31
	7	16,310	40,888	40
		54,425	162,411	34

Pig. L5. Superficial wounds, 2·5 cm². Hair was clipped short three days before wound making. Air at 20° C blown over wounds for 1 h after wound making. Serial sections at 10µ every fifth section measured.

Table 2. EPITHELIZATION AFTER AIR BLOWING

Time	Wound	Total length of epidermis (mm × 10^{-3})	Total length of section examined (mm × 10^{-3})	Percentage of epidermis
3 days	7	11,525	58,788	20
	8	13,363	72,510	18
	9	13,892	67,546	21
	10	13,233	63,992	21
	11	7,524	60,263	12
		59,537	323,099	18

Pig L8. Superficial wounds, 2·5 cm². Hair was clipped short three days before wound making. Air at 40° C blown over wounds for 30 min after wound making and a further 30 min, 5 h later. Serial sections at 10µ, every fifth section measured.

Thus the effect of blowing on an exposed superficial wound was to create a thicker than normal scab and delay epithelial migration. The results of these experiments support the view that the incorporation of part of the dermis into the scab is due to dehydration of that tissue.

A diagram summarizes the findings on the formation of the scab and epithelization under normal and experimental conditions (Fig. 1).

From a practical point of view, dry or moist conditions of the wound surface may prevail, or very frequently some intermediate state, depending on the type of dressing. Ventilation is obviously a significant feature of dressings in the treatment of wounds. Under the favourable conditions of animal experimentation, a moist wound heals most rapidly; but in human clinical practice a moist wound surface may not be desirable because of the risk of infection.

Many clinicians advocate the exposure treatment of wounds, particularly burns, where the aim is to encourage the formation of a natural protective scab. The experiments reported here suggest that the benefits of the natural scab can be achieved rapidly with air at a suitable temperature and pressure.

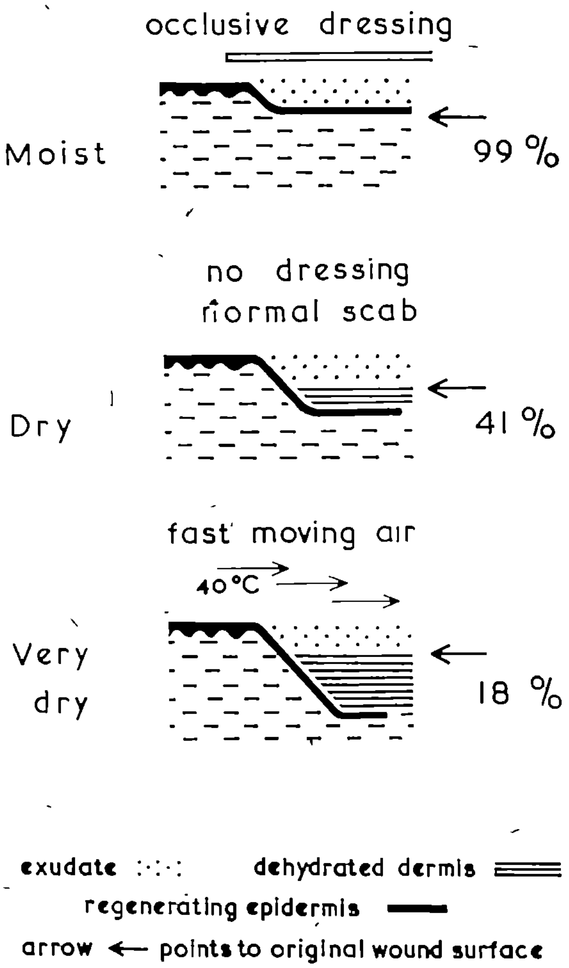

Fig. 1. Formation of the scab and the level of migration of epidermis in superficial wounds of the skin. Percentages represent the proportion of the wound area covered by new epidermis three days after the surface epidermis and the papillary layer of the dermis were removed from a 2·5-cm square of skin in young domestic pigs

Measurement of Length of the Fore-Cannon Bone in Live Sheep

MANY workers have sought to describe the size and shape of farm animals objectively by making measurements on live animals, while a number of others have proposed various combinations of measurements as a measure of body size and/or conformation, for example, Lush[1] (beef cattle), Cook *et al.*[2] (dairy Shorthorns), Berges[3] (beef cattle), Rae[4] (New Zealand Romney Marsh), Turner *et al.*[5] (Australian Merino), Phillips and Dawson[6], Hazel and Kline[7], Price *et al.*[8] (pigs). While the significance of cannon bone measurement as an index of total bone-weight of the carcass has been reported for sheep

(Hammond[9], Verges[10]; Palsson[11,12]) and pigs (McMeekan[13]), there are no reports of cannon bone measurements for live sheep being used as an index of carcass characteristics.

This communication describes a technique for measuring the fore-cannon bone length in live sheep. Its relation to the dressing percentage of lambs from Border Leicester × Merino ewes sired by Dorset horn rams is reported.

In 1961, during the course of investigations of grazing management practices by the C.S.I.R.O. Division of Plant Industry at the Dickson Experimental Station, Canberra, 66 August-drop lambs were reared. All the lambs were slaughtered at a mean weight of 70·6 lb. body-weight. (*S.D.* ± 2·89.) Carcass-weights ranged from 25 to 40 lb. Twenty-one of these lambs reached slaughter-weight on pasture, but owing to drying-off of the feed, 45 had to be finished by hand-feeding in a yard.

All measurements were made 24 h prior to slaughter. The foreleg is flexed to the maximum degree and one point of a steel caliper is placed on the lateral condyles of the distal end of the metacarpus while the other point is rested on the proximal end of the metacarpus at the knee joint. The distance between the caliper points is read off on a steel tape measure graduated in centimetres. All measurements were read to the nearest 0·1 cm and the mean of three consecutive readings was taken. Repeatability of these measurements for an observer was within 0·1 cm and between observers within 0·2 cm. The technique is simple and quick, taking, with two operators, less than 3 min for three consecutive readings.

After slaughter the left fore-cannon bones were collected, cleaned and oven-dried for 2 h at 100° C and their length measured to the nearest 0·1 cm with a vernier caliper. The correlation coefficient between live–dead cannon bone length for 61 observations is 0·80 ($P < 0{\cdot}001$). The regression equation expressing the relationship is $Y = 0{\cdot}9446X + 45{\cdot}8123$, *S.E.* 2·91 mm, where X = dead cannon bone length (mm) and Y = live cannon bone length (mm.).

For the 21 lambs finished on pasture the correlation coefficient between the live cannon bone length and dressing percentage is $-0{\cdot}55$ ($P < 0{\cdot}01$).

These are preliminary findings for the dressing percentages of pasture finished lambs. The relationship for the remaining 45 carcasses finished on a hand-feeding regime will be the subject of a later communication.

We thank the C.S.I.R.O. Division of Plant Industry, Canberra, for making available the material and actively assisting in the field aspects of this work. We particularly thank Dr. F. H. W. Morley, head of the Pastoral Agronomy Section of this Division, for advice, and Mr. H. W. Chapman, also of this Division, and Mr. A. Redpath, of Dickson Station, and the Canberra Abattoirs, for facilities.

Sound Reception in the Dogfish

Kritzler and Wood[1] succeeded recently in training a bull shark (*Carcharhinus leucas*) to respond to sine-wave sound signals emitted from a submerged loudspeaker. Responses occurred to frequencies between 100 and 1,500 c.p.s. A threshold curve shows that the animal was most sensitive to frequencies of 400–600 c.p.s. The sound source was (acoustically or visually) localized.

These experiments, affording valuable new evidence about the sensitivity of elasmobranchs to sound, lent new weight to the question how sound stimuli are perceived in these animals. On comparative physiological grounds, the participation of two groups of sense endings seems likely: (1) otolith organs and possibly other labyrinthine sense endings; (2) general cutaneous sense endings (touch or vibration receptors) in the outer skin. The lateral line organs and the ampullæ of Lorenzini have other special tasks; their participation in the reception of propagated sound waves seems unlikely, although stimulation may occur by local phenomena at short range of the sound source[2].

Up to now, there is no direct proof for sound reception by cutaneous sense endings in any fish[3]. As to the labyrinthine endings, Lowenstein and Roberts[4] found in electrophysiological experiments with *Raja clavata* that parts of the maculæ sacculi and utriculi as well as the macula neglecta responded to vibrations of the solid substratum on which the preparation was mounted. The highest effective frequency was found at about 120 c.p.s. Furthermore, Vilstrup[5] conditioned *Acanthias vulgaris* to the sound of a submerged motor horn and reports that the reactions were completely abolished after bilateral section of the acoustic nerve. Frequency and intensity of the sound used are not indicated. The sacculus is regarded as the main sound receptor. Previous experiments of Parker[6] on *Mustelus canis* had led to the conclusion that sounds would affect both skin and labyrinths but that the latter organs were the more sensitive of the two.

During a stay at the Zoological Station of Villefranche-sur-Mer (France) several dogfishes (*Scyliorhinus canicula*) were trained to respond to the tone of a submerged speaker by combining the sound stimulus with an 8-V alternating current from a submerged pair of electrodes as an unconditioned stimulus. Several click-free tone pips[7] of 1 sec duration each were given with intervals of about 0·5 sec before the unconditioned stimulus was added. The frequency of the tone used (resonance frequency of the speaker with its enclosing air-filled box) was about 180 c.p.s.; when picked up from the water via a barium titanate hydrophone, the tone appeared as a pure sine wave on the oscilloscope screen. The maximal intensity used initially was such that the vibrations could be felt by the submerged hand up to about 5 cm from the speaker; it was determined at this distance with the aid of a calibrated hydrophone at somewhat more than 500 dynes/cm^2. In order to keep the distance between fish and speaker constant, the animal was enclosed in a cylindrical, wide-mesh gauze cage made of plastic-covered wire. The cage measured 9–10 cm in diameter and was as long as the animal (48 cm). It was suspended horizontally in the midst of a large aquarium, the head of the dogfish pointing towards the speaker, which was suspended at the same depth at a distance of about 5 cm from the tip of the animal's snout. One eye of the fish was 'blinded' by covering the cornea with an oval piece of soft and thin opaque plastic, over which the eyelids were closed and sewn together with operation silk. The covered eye was at the side of the experimenter. The aquarium containing the fish was put on bicycle tubes to reduce penetration of sounds from the solid substratum.

After a number of trials, relatively weak but unmistakable sound reactions were observed. Sometimes there were certain fin movements but the most regular response was a short interruption of the respiratory rhythm, visible at the gill-slits. Now the sound intensity was reduced from trial to trial. Even at the lowest intensity used, when nothing could be felt by the submerged hand, still regular responses occurred. This intensity of about 90 dynes/cm² at the distance of 5 cm from the speaker or 45 dynes/cm² at the region of the animal's labyrinths was probably still considerably above threshold strength.

A trained dogfish was anaesthetized with 1·5 per cent urethane in sea-water. The root of the right acoustic nerve was dissected free from the ventral side via the mouth and cut near the medulla. After recovery, responses to the lowest sound intensity used previously were easily obtained. Now the left acoustic nerve was cut as described here. After this second operation, responses occurred only at definitely higher intensities and even then the reactions were irregular and very weak. The threshold intensity was determined at about 400 dynes/cm² when measured at a distance of 5 cm from the speaker. Before and after the operations short periods of training on lighting a nearby lamp (combined with the same electrical unconditioned stimulus) were inserted in order to test whether the animal was fit enough to respond to training stimuli in general. Light reactions occurred always regularly both before and after section of the second acoustic nerve.

These preliminary results—they are mainly based on experiments with a single dogfish, because the other specimens did not keep quiet long enough within their narrow cage—seem to indicate that perception of a tone of 180 c.p.s. occurs predominantly in the labyrinth. Only with great intensities do other sense-endings participate. The results are in accordance with those of Parker and Vilstrup.

This work has been supported financially by the Centre National de la Recherche Scientifique (Paris) and by the Netherlands Organization for the Advancement of Pure Research (Z.W.O.). Sound pressure determinations were made in the Physical Department R.V.O.—T.N.O. (The Hague).

Experimental Lathyrism in the South African Toad

EXPERIMENTAL lathyrism was produced originally more than a quarter of a century ago[1] by feeding rats seeds of the flowering sweet pea—*Lathyrus odoratus*. Since then a number of compounds, including semicarbazide, have been tested to determine their lathyrogenic activity. This experiment was to show the changes produced in larvæ of the South African toad (*Xenopus laevis*) when semicarbazide was added to the aquarium water.

Once the larvæ had reached developmental stages 48–58, that is, approximately 10 days before the break-through of the fore-limbs[2], they were divided into a control (250 larvæ) and test (350 larvæ) series. At this time, 4 µl. of a 0·005 per cent (w/v) solution of semicarbazide hydrochloride was added to each litre of aquarium water in which the test animals were. They were kept in this concentration until metamorphosis occurred, and both series were fed liver powder as required. Only 230 control animals and 280 of the test group survived until metamorphosis. Once metamorphosis was complete the toads were killed by adding excess ether to the aquarium water. There was marked retardation in body-growth in all test animals and they were much paler and weaker than the control animals. No gross dislocations, as described by Chang *et al.*[3,4] when using *Lathyrus odoratus*, were observed, although 76 test animals showed a compression fracture dislocation of the spine with resulting paresis. In 75 per cent of the test toads, histological examination revealed clefts between the connective tissue and the epiphysis of the tibio-tarsal joints when compared with the control animals (Fig. 1). The hip joints of 20 per cent of the test animals showed a degree of flattening of the upper femoral epiphysis with widening of the joint space when compared with the control (Fig. 2). This finding was constant on repeated sections and was not an artefact.

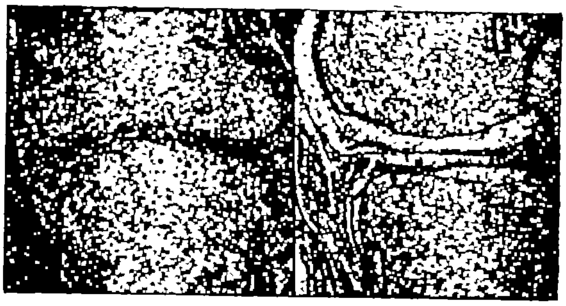

Fig. 1. Composite photomicrograph showing a tibio-tarsal joint of a normal toad (left) and a similar joint of a test animal (right). The presence of clefts between the connective tissue and epiphysis can be seen in the test toad. (picro-Mallory, × c. 85)

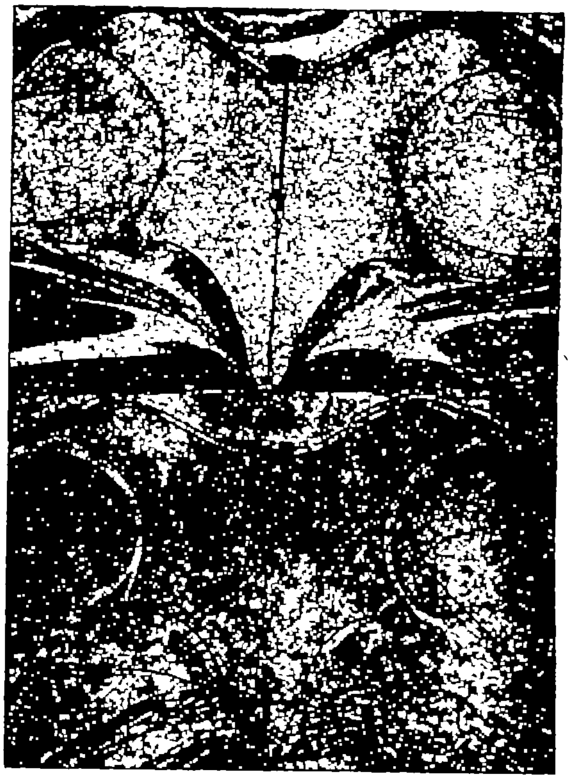

Fig. 2. Composite photomicrograph showing the pelvis of a normal toad and of a test toad in which is seen flattening of the upper femoral capital epiphysis on the right side. There is also widening of the joint spaces. The appearances are suggestive of what one would expect to see in humans with Perthes' disease. (picro-Mallory, × c. 45)

Previous workers, when dealing with *Xenopus laevis*, have used *Lathyrus odoratus* or β-aminoproprionitrile as their lathyrogenic agent. Here semicarbazide hydrochloride, a completely unrelated chemical compound, has been used with the production of virtually identical lesions. However, with semicarbazide, changes in the hip joints are reported with flattening of the upper femoral epiphysis and widening of the joint spaces. These changes could be similar to the appearances one would expect to find in humans suffering from Perthes' disease[5]. A Perthes-like appearance has been produced in rats on a lathyrogenic diet[6].

I thank Prof. T. Symington, Dr. A. Dick and Dr. B. M. Hobson for advice, and the last-named for supplying the larvae.

Root Parasitism in Santalaceae

THE Santalaceae are a family of some 250 species of mostly root semi-parasites. Although parasitism has been known in some species of this family, the existence of parasitism in the New Zealand representatives, *Exocarpus bidwillii* Hook. f. and *Mida salicifolia* A. Cunn., was not definitely known until recently[1]. Since then the parasitism of *E. bidwillii* has been examined in greater detail. The investigation has revealed many features not previously known concerning the parasitism of the plant and of the structure and development of its haustorium.

Like many santalaceous parasites, *Exocarpus* attacks a wide range of host plants and even roots of the same species. Occasionally also young haustoria are found attached to dead plant remains such as leaves, present in the surface soil layers. In the structure of its haustorium *Exocarpus* displays the general features of santalaceous haustoria, namely, cortical folds, collapsed layers and inverted conical flask-shaped form of the vascular tissue. Other characters it shares with only one or two other santalaceous haustoria. The presence of granules in the tracheary elements of the body of the haustorium is a feature which *E. bidwillii* only shares with *E. cupressiformis*[2] in so far as the Santalaceae are concerned. These granules only occur in the body of the haustorium and are not found elsewhere in the plant or in the vessels of the sucker. Their presence in the expanded part of the vascular tissue of the body suggests they may possibly be connected with the mechanism of the haustorium.

With the possible exception of *Buckleya quadriala*[3] and a few other santalaceous haustoria, the mature haustorium of *Exocarpus* differs from most haustoria in that it is a long-lived organ which exhibits secondary growth. According to Rao[4] most santalaceous haustoria are short-lived and seldom develop secondary tissues to any extent. In one striking feature the haustorium of *E. bidwillii* is distinct from all described haustoria of the Santalaceae. Whereas in santalaceous haustoria the sucker is usually described as a simple wedge or disk-like organ embedded in the tissue of the host root, that of *Exocarpus* is complex, consisting of a number of finger-like sucker branches extending along within the host root. In cross-section each sucker branch is wedge-shaped and deeply embedded in the host xylem. The development of the haustorium from shortly after initiation to the establishment of the mature organ was also followed. Haustoria arise laterally on *Exocarpus* roots in the primary state of growth, and develop chiefly from cortical tissue. They are exogenous in origin, there being no rupture of cortical tissue as with lateral roots.

Apart from ascertaining the nature of parasitism in *E. bidwillii*, the results of this work also suggest that some of the earlier work on santalaceous parasites was incomplete and that the conclusions and comparisons drawn may not be valid. This applies particularly to what is described as the mature haustorium. Where penetration is reported to be only superficial, as was originally described for *E. bidwillii*, further investigation might show that the haustorium investigated is merely a stage of development. Since young haustoria are usually more numerous and conspicuous than old, an insufficient examination of the root system has probably been responsible for immature haustoria being described instead of the mature organ. The assumption that most santalaceous haustoria are short-lived organs developing little secondary tissue could also be re-evaluated. Most santalaceous parasites are woody plants, and since their nutrition is apparently dependent in part on parasitism it seems peculiar that this demand should be satisfied by short-lived organs which seldom become intimately associated with host tissue for any length of time. Such a condition would scarcely appear to be successful parasitism.

Application of Gibberellic Acid to Strawberry Plants at Different Stages of Development

GIBBERELLINS are known to play an essential part in the metabolism of the strawberry plant from which they have been isolated chromatographically[1]. By spraying plants with gibberellic acid in the winter Singh *et al.*[2] advanced harvesting times by three weeks and increased yields. In the United States, Smith *et al.*[3] gave autumn applications which advanced fruit ripening by several days without affecting yields. Guttridge[4], however, reported that when gibberellic acid was administered in the autumn, fruit yields were reduced in Scotland.

To examine further the effect of different application times solutions of 12·5, 25, 50 and 75 p.p.m. gibberellic acid, to which had been added 'Agral 90' wetter, were sprayed over triplicate randomized plots of one-year old Royal Sovereign plants on March 6, April 13, or May 30 and at all combinations of these times. Plants were sprayed to run-off with volumes varying from 7 to 20 ml. of solution depending on the size at time of application.

On May 18 all treatments had accelerated flowering to an extent increasing with concentration and at the higher concentrations and multiple applications marked changes had occurred in the growth habit of the plants, the flower clusters being more numerous and borne on elongated peduncles extending well above the foliage. As 1962 was a year of late frosts many of these early flowers were killed.

The crop was harvested by picking three times weekly from June 27 until July 20 and numbers of fruits and their total weights were recorded. Total crop weights per treatment for the first two pickings and for the total harvest of 11 pickings are shown in Table 1.

Ripening was accelerated by several days, particularly at the higher concentrations of gibberellic acid, and the effect was greater with repeated applications. Total yields were not significantly improved but the number of berries increased with increasing concentrations up to 50 p.p.m., but tended to decrease with falling yields at 75 p.p.m. Sizes of fruits were normal with single applications of 50 p.p.m. or less and with the 12·5 p.p.m. concentration in the March–April and April–May applications. With the higher doses fruits were undersized, and, at the double and triple applications of 50 and 75 p.p.m., were noticeably elongated and substandard.

Table 1. EFFECT OF GIBBERELLIC ACID ON EARLY AND TOTAL WEIGHTS OF ROYAL SOVEREIGN STRAWBERRIES (KG FROM 18 PLANTS)

Application date	Gibberellic acid concentration (p.p.m.) 12½	25	50	75
March	0·72 (11·20)	0·68 (11·40)	0·83 (9·78)	1·05 (11·13)
April	0·32 (10·59)	0·49 (13·39)	0·74 (13·50)	0·80 (11·99)
May	0·45 (11·88)	0·50 (10·78)	0·52 (11·00)	0·60 (9·86)
March and April	0·32 (11·43)	0·76 (12·57)	1·15 (11·22)	1·53 (9·12)
March and May	0·36 (11·69)	0·78 (10·92)	1·05 (10·48)	1·44 (8·55)
April and May	0·34 (10·69)	0·81 (12·53)	0·78 (14·10)	1·10 (10·02)
March, April and May	1·05 (10·88)	1·24 (11·44)	1·58 (10·38)	1·69 (8·00)
Untreated		0·27 (10·30)		

Note. Complete harvest weights given in parentheses.

At the optimum treatment-levels of 25 or 50 p.p.m. in April or April–May the financial return from the crop exceeded that of untreated fruit by up to 25 per cent. A commercial grower could expect under these conditions an additional profit of £200 per acre at a cost which is only a fraction of this. The exact cost of chemical will depend on the spray technique involved, and it may be preferable to give an all-over spray at twice the experimental rate to ensure adequate cover rather than to attempt application to individual plants as was done in this experimental trial.

Nucleic Acids and Other Characteristics in Biotin-deficient and Normal *Protomyces inundatus* Cultures

IN the course of a taxonomic investigation into the genus *Protomyces*[1], it was found that in the absence of biotin the fungus grows much slower than the control, and the budding spores have a clumpy appearance. In view of the recent demonstration that biotin deficiency has been found to have a profound effect on the synthesis of nucleic acids and proteins in *Saccharomyces cerevisiae*[2], it was thought worth while investigating the effect of biotin deficiency in *P. inundatus*.

Diploid cultures of *P. inundatus* were grown either on Lilly and Barnett's[3] basal semi-synthetic liquid medium or on the same medium minus biotin. The same methods used by Valadon *et al.*[4] were used for the estimation of nucleic acids, metaphosphate, insoluble nitrogen, dry weight and volume in this experiment. Samples were removed for analysis at intervals between 8 and 18 days' incubation. The results were converted on a per cell basis[4] by counting the cells in a small aliquot by means of a hæmocytometer.

The results obtained are presented in Table 1. The values per cell of all the characteristics investigated are higher in the cultures with, than in those without, biotin. It has been shown[4] for a normal culture that from 14 days onwards there is a decrease in DNA and RNA per cell; after 8 days'-growth the values per cell are low, gradually increase until they reach a maximum on the fourteenth day and then fall off. In the cultures without biotin DNA and RNA per cell increase up to the tenth day and then rapidly decrease; the cells are not observed to divide, they increase in weight until the twelfth day and after sixteen days the number of living cells decrease rapidly. In the normal cultures, however, cell number per ml. increases up to the fourteenth day when the cells stop dividing but are growing and are still growing at the end of the experiment.

Metaphosphate per cell goes down rapidly when cell division has stopped in the normal cultures after 14 days. Metaphosphate per cell seems to be correlated with the rate of cell division especially as metaphosphate per cell stays at a relatively constant low level in the cultures without biotin in which no cell division is observed. Further investigation of this relationship seems worth while.

Volume per cell increases in step with dry weight and insoluble nitrogen in the normal cultures while they increase up to the fourteenth day in cultures without biotin.

The ratio RNA/DNA was found to be constant[4], and the same constancy is found in the ageing normal cultures but in those without biotin the ratio RNA/DNA is slightly smaller. In agreement with Ahmad *et al.*[2] a decrease is found in the values of nucleic acids per cell in biotin-deficient cultures and these differ significantly from those in normal cultures. Total insoluble nitrogen per cell, on the other hand, is shown to increase up to the twelfth day in the biotin-deficient cultures and is still increasing after 18 days in the normal cultures. This is comparable with the results obtained by Valadon *et al.*[4], who showed that insoluble nitrogen per cell was increasing even though RNA and DNA per cell were decreasing.

The fact that RNA per cell in *P. inundatus* decreases after 12 days in normal cultures while total insoluble nitrogen still increases is not inconsistent with the well-known statement that RNA takes part in protein synthesis[5]. The biotin-deficient cultures, too, show the same thing, RNA per cell decreases after 10 days while insoluble nitrogen per cell is increasing. It was not possible to estimate the various characteristics of very young cultures as the fungus does not grow fast. Attempts are being made to obtain a large number of cells as soon as possible after the cultures are established and it will be interesting to find out if there are any relationships between nucleic

Nitrogen Source in Fungal Decomposition of Wood

It is a well-known fact that the nitrogen content of the medium is one of the limiting factors in fungal decomposition. Two experiments were carried out in order to determine whether the effective destruction of wood by *Merulius lacrymans* is sustained solely by the amount of nitrogen originally present in the wood, or whether any fixation of nitrogen from the atmosphere might possibly occur. Small cubes of wood were used in Exp. 1 and wood shavings in Exp. 2; the procedure, largely the same in both, was as follows:

A heap of cubes or shavings from pine sapwood, placed on a table and protected from dust, was left in the atmosphere of an ordinary room until, after about a week, constant weight was reached. Samples of 5 or 10 g air-dry cubes or shavings were transferred to Kjeldahl flasks and sterilized. After inoculating every second flask with *Merulius*, all flasks were stored, necks horizontal, at 24° in a constant-temperature room. During storage both test and control flasks received at intervals the same amounts of sterile water to keep them moist. At the conclusion of the experiments all the control flasks were still quite free from fungal growth and the cubes or shavings seemed quite fresh. The inoculated wood was fully decomposed leaving only some brown powder in the mycelium.

After 2 (in Exp. 1 only), 4, 6 and 8 months of storage the contents of three control flasks and three inoculated flasks were subjected to the Kjeldahl procedure. As no clear influence of storage time could be detected in the nitrogen figures, the mean values are given in Table 1.

Table 1

	No. of flasks (excluding failed analyses)	Average N-content mg/air-dry wood	Deviation $\pm\sqrt{\frac{\Sigma x^2}{n}}$
Exp. 1, wooden cubes:			
Inoculated	14	0·71	0·13
Controls	13	0·57	0·07
Exp. 2, wood shavings:			
Inoculated	8	0·48	0·05
Controls	8	0·445	0·05

The difference in the final nitrogen content in Exp. 2 is not significant, and in Exp. 1 only barely so; thus scarcely lending much support to any theory of nitrogen fixation. The weak point of the method, however, is obviously the heterogeneity of the wood samples.

Before proceeding further with these long-term experiments we would like to invite criticisms of the method. Apart from greatly increasing the number of trials, there are perhaps alternative procedures which might be adopted. The possibility of using sawdust, which might be more homogeneous, has been considered but we have noticed that the growth of *Merulius* was better on the cubes than on the shavings but worse in sawdust. A method of promoting faster growth on woody materials is desirable, thereby decreasing the experimental time.

(Drying the material at higher temperatures was avoided, owing to irreversible drying-swelling hysteresis which was apparent in some preliminary experiments.)

ENTOMOLOGY

Origin of Wings in Insects

The wings of insects are outgrowths of the thorax, quite independent of the limbs. The difficulty of picturing their origin in evolution is that of imagining what selective value they could have had during the primitive stages of their development.

The view that flight started from the surface of the sea by the use of fin-like appendages adapted for swimming[1] has found little support. By analogy with the evolution of wings from the fore-limbs of vertebrates, the wings of insects are commonly supposed to have arisen as fixed organs used for gliding[2,3]. The occurrence of fixed paranotal lobes in fossil Palaeodictyoptera is often held to support this speculation.

Walton[4] claimed that the wings of insects originated from basal parapodial appendages of Polychaetes; and Raw[5], in proposing likewise their evolution from the dorsal swimming lobes of the parapodia, pointed out that if that were so they would be already furnished with the muscles used for swimming. Pringle[6], on the other hand, suggests that flight was first evolved in an insect of large size, perhaps a leaping insect, which developed muscles that could control the inclination of the paranotal planes used for gliding; only at a later stage were muscles developed which could move the wings up and down and thus lead to the evolution of slow flapping flight.

The purpose of this communication is to put forward a third suggestion—that the wings may have been evolved neither in aquatic ancestors, nor in large earth-bound insects, but in small aerial species.

As is well known, there is a large aerial fauna of insects and other arthropods extending up into the sky for some thousands of feet[7]. Tetranychid mites make regular migrations into the orchards during the summer months, on days when there is a gentle breeze, by means of silken threads; spiders are carried great distances in the same way. Among the insects it is mainly winged forms which make these aerial migrations; but small hairy caterpillars, such as those of the gypsy moth, can be carried many miles by the wind[8,9]; one human flea, *Pulex irritans*, was taken at a height of 200 ft.; and wingless Thysanura, Collembola, young stages of Hemiptera and Orthoptera. larvae of Coleoptera, Lepidoptera and Diptera, and great numbers of wingless ants have been captured at heights up to 5,000 ft.[7]. Such flights must have been common among the earliest terrestrial arthropods.

Although many arthropods possess notal extensions, it is only in the wings of insects and the 'pteromorphs' of certain Oribatid mites that these extensions are hinged[10]. Oribatid mites figured among the arthropods collected in the sky by Glick[7], but they were not abundant.

These aerial migrations are of undoubted selective value in securing the dispersal of many of the species concerned. It is not difficult to imagine conditions under which the provision of light cuticular expansions from the thorax would facilitate 'take-off'. The existence or appearance of muscles which could twist these light planes, as suggested by Pringle[6], would increase their efficiency in take-off and might even afford some control during landing. Flapping muscles, even of the most primitive type, would increase the efficiency of both take-off and landing still further—although, of course, the greater part of the flight would be wholly passive. In short, very small steps towards the evolution of completely functional wings could at once have selective value.

It is worth pointing out that among the Aphids, which are highly efficient fliers and which migrate in vast numbers, often for hundreds of miles[11], it is only at the point of departure and at the point of landing that their movements are under their own control. Once they become well and truly air-borne the Aphids, and even locusts, are at the mercy of convection currents and winds[12].

I thank Prof. C. F. A. Pantin, Dr. J. Smart, Dr. J. S. Kennedy and Dr. A. D. Lees for comments, notably for references to the literature.

Vitamin Requirements of the Silkworm

KNOWLEDGE of the nutritional requirements of the silkworm, *Bombyx mori* L., has recently been accumulating by the use of artificial diets[1,2], and more recently successful rearing on synthetic diets[3,4] and the establishment of aseptic culture[4,5] have been reported. Artificial diets have been used for the demonstration of the requirements for ascorbic acid in this insect[3]; but so far not for the compounds of vitamin B group. From the experiment on growth inhibition with antimetabolites it has been shown that nicotinic acid and pyridoxine are necessary for the silkworm[6]. In this experiment either antimetabolite or this plus vitamin was supplemented on fresh mulberry leaves to induce growth retardation by antimetabolite or growth resumption, but never completely, by supplementing vitamin. This preliminary communication reports the requirements for vitamin B compounds, demonstrated by means of aseptic culture on synthetic diets.

The composition of synthetic diets, somewhat modified from previous ones[3,4], is given in Table 1. The diets contained 0·8 per cent of mulberry leaf extracts, which had been proved to be required for good growth and feeding[7]. The procedure of separation of leaf extracts is outlined in Fig. 1. Each of the diets lacked one of the vitamins listed in Table 2. The preparation of diets has already been described in detail[3,4]. The larvæ were reared aseptically by the use of Erlenmeyer's flasks from hatching. The methods of autoclaving of diets and sterilization of egg surface have also been reported previously[4,5]. After 25-day culture, the flasks were opened and the number of surviving larvæ, by each instar, was counted. The instar progression of larvæ, both surviving and dead, was determined by observing head-capsule width.

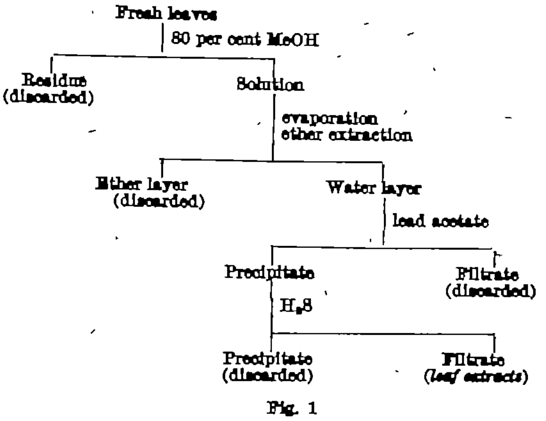

Fig. 1

Table 1. COMPOSITION OF THE DIET

Substance	Dry diet %
Starch (potato)	15
Glucose	15
Soybean meal*	25
β-Sitosterol	1
Ascorbic acid	1
Wesson's salt mixture	1
Cellulose powder	41·2
Mulberry leaf extracts	0·8
	100·0

* Hexane-extracted soybean meal (Ajinomoto Co., Ltd., Yokohama Factory) was washed first with ethyl ether, then with ethyl alcohol, respectively for 24 h.

1·5 ml. of distilled water were added per 1 g of the dry diet.

Table 2. COMPOSITION OF THE VITAMIN MIXTURE

Vitamin	Amount added to 6 gm. dry diet (mg)
Biotin	0·02
Calcium pantothenate	0·2
Choline chloride	2·0
Folic acid	0·02
Inositol	2·0
Nicotinic acid	0·2
Pyridoxine hydrochloride	0·1
Riboflavin	0·1
Thiamine hydrochloride	0·1
Total	4·74

Table 3. GROWTH AND DEVELOPMENT OF THE SILKWORM ON DIETS LACKING VARIOUS VITAMINS

Diet	Initial No. of larvæ	Number of larvæ reaching through various instars during 25 days				No. of surviving larvæ when flask opened	Mean body-weight (mg)
		Second instar	Third instar	Fourth instar	Fifth instar		
No vitamin	21	—	—	—	—	0	—
	20	—	—	—	—	0	—
	19	5	—	—	—	0	—
All vitamins	18	13	12	11	5	12	126·8

Biotin-free	20	10	9	8	—	8	117·6
	21	14	13	12	3	12	117·8
Folic acid-free	22	13	13	10	3	13	124·1
Inositol-free	19	16	14	11	2	12	76·6
Nicotinic acid-free	19	15	2	—	—	1	2·9
	20	13	—	—	—	0	—
Pantothenic acid-free	17	16	—	—	—	1	Not weighed
	23	20	—	—	—	2	
	22	16	—	—	—	0	—
Pyridoxine-free	22	11	—	—	—	0	—
Riboflavin-free	20	18	14	12	3	11	120·8
	17	8	7	4	1	7	57·4
Thiamine-free	20	17	12	10	1	12	69·7
	19	15	14	8	1	12	44·7
	19	19	18	14	2	16	89 6

Table 3 shows one of the results obtained. On the diet without any added vitamin most of the larvæ died before reaching the second instar and a few reaching the second instar died shortly after moulting. The addition of all vitamins resulted in fairly good growth and development and some of the larvæ reached the fifth instar during 25 days. Even on such diets a considerable number of larvæ died by the end of the experimental period. A relatively high mortality in the aseptic culture has been recognized even on diets containing leaf powder or leaf juice[4,5]. The omission of nicotinic acid, pantothenic acid, or pyridoxine affected growth adversely. In these cases the larvæ reached the second instar but did not develop to the third instar, except for only a few in the case of nicotinic acid. On the diet lacking thiamine weight increase was somewhat reduced, but not necessarily decisive. Lack of either biotin, folic acid, riboflavin, or inositol did not result in any noticeable effect during the present developmental period. No significant result was obtained when choline was omitted.

Thus, it is concluded at present that nicotinic acid, pantothenic acid, and pyridoxine are essential dietetic constituents for normal growth and development of the silkworm and the effect of the lack of one of them appears in the younger larvæ. The omission of riboflavin or biotin did not suppress the growth (Table 3), which, however, are almost commonly required by insects[8]. Whether or not the lack of those vitamins might affect the older larvæ or in later stages beyond 25-day culturing period must be determined in future. Hexane-extracted soybean meal, one of the possible sources of vitamin contamination, was washed with ether and afterwards with alcohol, as stated here. There is almost no possibility of vitamin contamination from leaf extracts.

When the larvæ were reared under non-sterile conditions by means of Petri dish, larval growth and development were somewhat improved even on vitamin-deficient diets, that is, a few larvæ reached the third instar, but did not develop further and finally all died. Even in the case of the omission of pantothenic acid or pyridoxine, larvæ grew better than in the case of aseptic culture. It is thus concluded that micro-organisms are partly the source of vitamin supply, as has been suggested[6,4].

Further experiments on vitamin requirements are being carried out and the details will be published in the *Bulletin of the Sericultural Experiment Station*.

Tests for Multiple Insemination in *Anopheles gambiae* Giles

IT has been shown that in *Aedes aegypti*[1,2], three forms (*pipiens*, *fatigans* and *molestus*) of the *Culex pipiens* complex[3], and *Anopheles gambiae*[4], one male is capable of inseminating more than one female. On the other hand, in *C. fatigans* and *C. molestus*, one female is fertilized by only one male[5]. Multiple mating of the female has been reported in *Aedes aegypti*[2,6] and inferred in *Anopheles albimanus*[7]; but it is not certain whether multiple *insemination* was consequently accomplished. Mating in mosquitoes may sometimes be ineffective, resulting in no discharge of spermatozoa into the spermatheca[4]. The following observations were undertaken to test whether one *Anopheles gambiae* female may be inseminated by more than one male.

The observations were made on two genetically distinct laboratory strains of *A. gambiae* maintained at the Ross Institute in London, namely: (1) 'Kano *RR*', which is homozygous 'Dieldrin'-resistant; and (2) 'Lagos *SS*', homozygous insecticide-susceptible. The adults of Lagos *SS* are killed by exposure for 1 h to 0·4 per cent 'Dieldrin'; while those of Kano *RR* survive 4·0 per cent. Cross-fertilization between the two strains produces hybrids which are killed by exposure to 4·0 per cent 'Dieldrin', but survive 0·4 per cent. However, a very small percentage of the hybrids may sometimes survive exposure to 4·0 per cent 'Dieldrin', while experimental handling may account for mortalities of 1·0–2·0 per cent. In the present observations mortalities and survival rates of less than 5·0 per cent are believed to have been due to this. Insecticide-resistance was used as a genetic marker. The experimental results were then compared with the expected distribution of this marker characteristic in the progeny of individual females.

Lagos *SS* females were caged together with Lagos *SS* and Kano *RR* males, in a ratio of one female to two types of males. After mating and feeding the females were isolated for oviposition. The progeny of each female was bred out separately and the resulting adults then tested for resistance to 0·4 per cent 'Dieldrin'. The results are shown in Table 1.

Table 1. LAGOS *SS* ♀♀ × (LAGOS *SS* + KANO *RR*) ♂♂

No. of parent females	Progeny (both sexes) exposed to 0·4% 'Dieldrin' Total	Alive	Dead	Mortality (%)
6	222	222	0	0·0
1	132	131	1	0·8
1	64	60	4	6·3
1	35	32	3	8·6
1	15	4	11	73·3
8	170	0	170	100·0

In 14 out of 18 females, all progeny from a single female were clearly of one type or the other, never mixed. But the progeny of 3 (those between the dotted lines) of the remaining 4 females was distinctly mixed, indicating multiple fertilization.

Kano *RR* females were caged together with Kano *RR* and Lagos *SS* males. The foregoing procedure was followed and the progeny was tested for resistance to 4·0 per cent 'Dieldrin'. The results are shown in Table 2. The progeny of 6 females out of 22 was not mixed. However, in only 8 (those between the dotted lines) of the rest was the mixed progeny thought to have been due to multiple fertilization.

Table 2. KANO *RR* ♀♀ × (KANO *RR* + LAGOS *SS*) ♂♂

No. of parent females	Progeny (both sexes) exposed to 4·0% 'Dieldrin' Total	Alive	Dead	Mortality (%)
4	178	178	0	0·0
1	102	100	2	2·0
1	101	99	2	2·0
1	48	47	1	2·1
1	40	39	1	2·5
1	81	79	2	2·5
1	27	26	1	3·7
1	17	16	1	5·9
1	102	94	8	7·8
1	51	47	4	7·8
1	91	83	8	8·8
1	10	9	1	10·0
1	46	38	8	17·4
1	77	59	18	23·4
1	30	2	28	93·3
1	21	1	20	95·2
1	91	3	88	96·7
2	65	0	65	100·0

Kano *RR* females were first caged together with their own males only. Those which had been fertilized, as shown by the production of viable eggs, were afterwards placed in another cage with virgin Lagos *SS* males in a 1 : 1 ratio. After sufficient contact between the sexes, the females were allowed to oviposit separately again and their adult progeny tested for resistance to 4·0 per cent 'Dieldrin'. The results are shown in Table 3. The progeny of all the females was undoubtedly of one kind, indicating lack of re-insemination by the Lagos *SS* males.

Table 3. KANO *RR* ♀♀ PREVIOUSLY INSEMINATED BY THEIR OWN MALES × LAGOS *SS* ♂♂

No. of parent females	Progeny (both sexes) exposed to 4·0% 'Dieldrin' Total	Alive	Dead	Mortality (%)
6	245	245	0	0·0
1	154	153	1	0·6
1	127	126	1	0·8
1	116	115	1	0·9

These observations clearly indicate that multiple insemination of females is rare in *Anopheles gambiae*. It is also clear that even when this occurs the fertilization of the ova of any one batch is unequal, the progeny being preponderantly of one kind, never on a 50 : 50 basis. This may well indicate possible differences in the fertilization mechanisms of spermatozoa produced by different

A. gambiae strains. It has been suggested[4] that the inhibition of multiple insemination by the female mosquito could operate as an effective isolating mechanism, barring hybridization between closely related sympatric species, races or strains. On the other hand, having once mated with a 'foreign' male, the potentiality of the particular female to contribute to the next generation of her own kind will be inhibited.

I thank Mr. G. Davidson for advice.

Function of the Areæ Porosæ of Ixodid Ticks

The function of the areæ porosæ of the dorsal side of the basis capituli of the female ixodid tick was unknown for a long time. The tradition of considering it as an organ of unknown function has apparently been so well accepted by acarologists that, for at least the past 50 years, no attempt seems to have been made to elucidate the function. The interest of most acarologists in the porose area seems to be restricted to using its size and shape as an auxiliary character for specific diagnosis.

It can now be shown that the areæ porosæ are the outlets of the glands recently discovered and described[1].

Feldman-Muhsam and Havivi reported on two previously undescribed groups of accessory glands in the vicinity of Gené's organ, in gorged females of *Hyalomma excavatum*, *Rhipicephalus sanguineus* s.l. and *Boophilus annulatus*. The glands become evident soon after the onset of feeding, and attain full development by the time oviposition begins. It was also noted that these glands were not found in *Ornithodoros tholozani*.

It should be added that the glands were also found in *Ixodes ricinus* and *Dermacentor albipictus*. These additional observations suggest that these glands are present in all Ixodidae, and are absent in Argasidae.

Further examination of the morphology and development of these glands showed that the very thin and elongated ducts of these glands terminate in the areæ porosæ. Each gland is apparently connected to a separate pore of the area porosa; the number of glands corresponds to the number of pores. The relationship between the areæ porosæ and these glands explains why there are no areæ porosæ in Argasidae.

Experimental interception of the flow of the glandular secretion by obstruction of the orifices of the areæ porosæ interfered with the normal functioning of Gené's organ and consequently with oviposition.

During oviposition Gené's organ comes in close contact with the basis capituli; it is protruded and retracted for the laying of each egg. Thus, during oviposition Gené's organ is protruded and retracted on the average about 2,000 times in *Boophilus annulatus*, about 3,000 times in *R. sanguineus* s.l., about 5,000 times in *D. andersoni*, and 8,000–15,000 times in some species of *Hyalomma*. It is quite obvious that such a mechanism needs a lubricating system to function smoothly.

The obliteration of the areæ porosæ showed clearly that Gené's organ is incapable of functioning without the secretion of the recently described glands.

When the orifices of the areæ porosæ are destroyed, Gené's organ stops its movements and often remains wholly or partly stuck to the basis capituli. It is therefore assumed that the main function of the glands is most probably the lubrication of the evagination–invagination mechanism of Gené's organ.

This investigation was supported by research grant No. 4531 from the National Institutes of Health, U.S. Public Health Service.

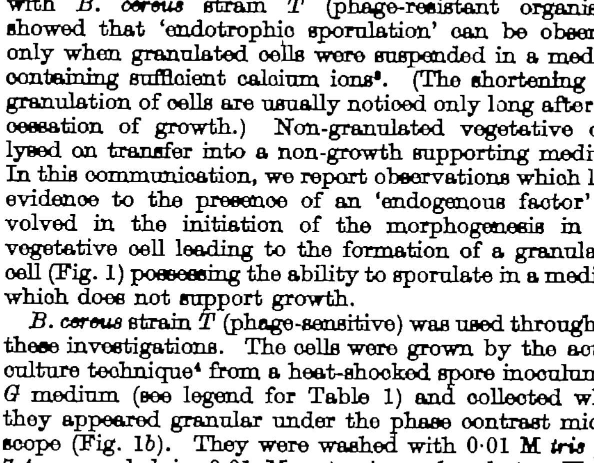
MICROBIOLOGY

'Endogenous Factor' in Sporogenesis in Bacteria

Extensive investigations on the morphological changes during sporogenesis have afforded valuable information about this phenomenon[1]. The initiation of sporulation can be better understood if the metabolic events during the transition from a vegetative cell to its sporulating phase are known. Several attempts have been made to investigate the physiology of growth distinct from sporulation. Foster *et al.*[2] found that when vegetative cells of *B. mycoids* were removed from the complex growth media before the point of maximal growth and transferred to distilled water, they formed spores. This was termed 'endotrophic sporulation'. But experiments with *B. cereus* strain *T* (phage-resistant organisms) showed that 'endotrophic sporulation' can be observed only when granulated cells were suspended in a medium containing sufficient calcium ions[3]. (The shortening and granulation of cells are usually noticed only long after the cessation of growth.) Non-granulated vegetative cells lysed on transfer into a non-growth supporting medium. In this communication, we report observations which lend evidence to the presence of an 'endogenous factor' involved in the initiation of the morphogenesis in the vegetative cell leading to the formation of a granulated cell (Fig. 1) possessing the ability to sporulate in a medium which does not support growth.

B. cereus strain *T* (phage-sensitive) was used throughout these investigations. The cells were grown by the active culture technique[4] from a heat-shocked spore inoculum in *G* medium (see legend for Table 1) and collected when they appeared granular under the phase contrast microscope (Fig. 1*b*). They were washed with 0·01 M *tris* *p*H 7·4 suspended in 0·01 M potassium phosphate *p*H 6·8 (1/50 vol. of original medium) and sonicated in the Raytheon sonicator for 10–12 min. The broken cells and cell debris were removed by centrifugation at 15,000*g* for 15 min. Most of the protein in the clear supernatant was removed by acidifying with 1 N hydrochloric acid and centrifuging off the precipitate. The 'active principle' was



a *b*

Table 1. THERMAL STABILITY OF SPORES OBTAINED UNDER VARIOUS CONDITIONS: ANALYSES AFTER 24 H

No.	Suspending medium	% Spores (microscopic)	Viable cells/ml. before heating*	Viable cells/ml. after heating	% Survival
1	*G* medium	99	$2 \cdot 1 \times 10^8$	$2 \cdot 3 \times 10^8$	100
2	*A* medium	5	$2 \cdot 1 \times 10^6$	—	—
3	*A* medium + active principle	95	$6 \cdot 5 + 10^7$	$5 \cdot 4 \times 10^7$	83

Composition of the *G* medium in percentage. $(NH_4)_2SO_4$, 0·2; K_2HPO_4, 0·05; $MnSO_4.H_2O$, 5×10^{-3}; $CaCl_2$, 8×10^{-3}; $ZnSO_4.7H_2O$, 5×10^{-4}; $CuSO_4.5H_2O$, 5×10^{-4}; $FeSO_4.7H_2O$, 5×10^{-5}. Yeast extract, 0·2, and glucose, 0·1.

A, medium consists of all the minerals in *G* medium and the following (percentage solution): sodium citrate, 0·05; sodium acetate, 0·05; and sodium glutamate, 0·05.

* The number of cells was the same in all flasks at the start of the experiment. The low viable counts in No. 2 denote extensive lysis and loss of viability. The difference between No. 1 and No. 3 is due to the ability of *G* medium to support growth.

found to be present in non-protein fraction and was tested in the following manner. Vegetative cells (Fig. 1*a*) grown as usual in *G* medium were transferred to a non-growing medium (medium *A*) and allowed to sporulate in the presence of aliquots of the cell extract. The total solids present in the cell extracts added to a 10 ml. of test culture varied between 100–200 μg. The results obtained in a typical experiment are shown in Table 1. The vegetative cells in the absence of the active principle had a tendency to remain vegetative for a few hours and eventually lysed, whereas in the presence of the extract they were converted into granulated cells within 2–3 h and later formed spores. The activity of the extracts was relatively heat-stable but labile under alkaline conditions. Our experiments offer support for Murrell's[5] speculation on the initiation of sporogenesis by a "specific endogenous substance having a hormone-like activity".

Temperature-dependent Variation in the *Vi*-typing Reactions of Strains of *Salmonella typhi*

IT has been found that the specific *Vi*-phage sensitivity patterns of several of the types belonging to the *Vi*-phage typing scheme[1] are easily modified by changing the temperature of incubation of the typing plates. The types so far found to display this phenomenon are: *D*1, *D*4, *D*7, *D*8, *D*9 and *D*10. In general, each type exhibits its maximum specificity at 38·5° C (the standard temperature for *Vi*-phage typing). As the temperature is lowered, this specificity is progressively reduced. The diminution in the specificity of a given type is shown by a broadening of the sensitivity spectrum of the strain to the *Vi*-typing phages. This broadening is maximal at 36·5° C. All the types concerned are known to be lysogenic, and their structural formulæ[2] and sensitivities to a range of typing phages at 36·5° C and 38·5° C are shown in Table 1.

The current type strain of *D*1 (which was supplied by Dr. P. R. Edwards, and which we call *D*1-E) is fully sensitive to all the phages shown over a wide range of temperatures. This culture was substituted for the original type strain of Craigie and Yen[1] (called here *D*1-C) because of the relative insensitivity of the latter to several of the typing phages of this group, especially phage *D*6. It has been found that the difference in the *Vi*-typing reactions of these two strains are due to differences in the type-determining phages[3] which they carry. These two phages, called *d*1-E and *d*1-C, respectively, are serologically identical, and a culture of type *A* lysogenized with either phage becomes resistant to the other. They differ only in their type-determining properties. The type-determining phages isolated from types *D*1-C, *D*4 and *D*7 are indistinguishable from each other and we use the symbol *d*1-C for all of them.

Read and Ferguson[4] have shown that the typing reactions of types *D*8, *D*9 and *D*10 are determined by double lysogeny and they give their structural formulæ as *A*(*d*8α)(*d*8β), *A*(*d*9α)(*d*9β) and ?(*d*10α)(*d*10β), respectively. I have confirmed the double lysogeny, but find that the three so-called 'α' phages are indistinguishable from *d*1-C. I therefore propose to abandon the 'α' designations and to call each of these phages *d*1-C. It then becomes unnecessary to use the 'β' symbol to distinguish the second temperate phage of each type, and I suggest that this, too, should be dropped. Phages '*d*8β' and '*d*9β' are unrelated to each other or to *d*1-C and *d*1-E, but '*d*8β' and '*d*10β' appear to be identical. I shall therefore call the last two phages *d*8. The structural formulæ which I propose for types *D*8, *D*9 and *D*10 are, therefore, *A*(*d*1-C) (*d*8), *A*(*d*1-C) (*d*9) and ?(*d*1-C) (*d*8), respectively, in place of those published earlier[4,5].

The temperature dependence of the specificity of most of these *Vi*-types seems to be largely due to the phage *d*1-C which they all carry. Phages *d*8 and *d*9, however, also play some part in determining the temperature sensitivity. Cultures with the structures *A*(*d*8) and *A*(*d*9) have been made, and it has been found that the typing reactions of these are also sensitive to temperature variation.

The increased resistance at 38·5° C of type *D*1-C, or *A*(*d*1-C), to several of the *Vi*-phages is the result of a reduction in both size and numbers of the plaques formed. The temperature of incubation during the first 4 h after the typing phages have been applied determines the final reactions. Thus a culture incubated for 4 h at 38·5° C followed by 16 h at 36·5° C will react as if it had been incubated at the higher temperature throughout. A change of temperature as small as 0·5° C during the first 4 h, or a shortening of this initial incubation period by as little as ½ h, is reflected in the final typing reactions.

One-step growth experiments have been performed using type *A* and cultures *A*(*d*1-C) and *A*(*d*1-E) as hosts

Table 1. EFFECT OF TEMPERATURE ON THE SENSITIVITY OF CERTAIN TYPE-STRAINS OF *Salmonella typhi* TO THE GROUP *D* *Vi*-TYPING PHAGES AT ROUTINE TEST DILUTION (REF. 12)

* The use of the '?' symbol signifies that the non-lysogenic precursor is not known.
CL, confluent lysis; SCL, semi-confluent lysis; +, + +, + + +, increasing numbers of discrete plaques.

Table 2. RESULTS OF ONE-STEP GROWTH EXPERIMENTS WITH *Vi*-PHAGE *D*1 IN DIFFERENT HOSTS AND AT DIFFERENT TEMPERATURES

Host culture	Growth temperature (° C)	Latent period (min)	Rise period (min)	Burst size
Type *A*	35·0	38	15	100
	39·5	37	17	160
A(*d*1-E)	35·0	37	18	40
	39·5	35	18	65
A(*d*1-C)	35·0	37	35	12
	38·0	36	40	4
	39·5	?	?	1–2

for *Vi*-typing phage *D*1. The burst size in *A*(*d*1-C), which is considerably lower than that in type *A* and *A*(*d*1-E) at all temperatures, is progressively reduced as the temperature is raised from 35·0° C to 39·5° C. In *A* and *A*(*d*1-E) the burst size of phage *D*1 increases with the rise in temperature. The latent period at all temperatures is the same in each of the cultures, but the rise periods with *A*(*d*1-C) are longer than with the other two cultures (Table 2).

Temperature sensitivity of *Vi*-typing reactions was first observed by Craigie, who found that type *N* of *Salmonella typhi* cross-reacted with several *Vi*-phages of the *D* group. The cross-reactions were abolished by incubation above 38·0° C (ref. 6).

The resistance to viral infection of several plant species is increased by raising the temperature at which the plants are grown[7] and it is possible to cure some virus-infected plants by heat therapy[8]. A similar phenomenon has been observed in animal viruses. For example, it has been shown that the likelihood of survival of mice infected with the MEF_1 strain of poliovirus is increased when the environmental temperature is raised[9]. The Lwoffs[10] have found that raising the temperature of incubation reduces the viral yield of tissue cultures infected with attenuated vaccine strains of poliovirus more so than that from cultures infected with a highly neurovirulent wild strain. Mutants of this virus have been isolated which develop preferentially at either a high or a low temperature, and it has been found that the former are usually the more virulent[11a,b].

The phenomenon reported here resembles that found in plants and animals but differs from them in that it is not the intrinsic phage resistance of the bacterial host which is modified, or the virulence of the infecting phage. It is essential that the bacterium carries a prophage such as *d*1-C which confers, on the phage-host cell complex, temperature sensitivity in relation to multiplication of the superinfecting *Vi*-phage.

Minimum Requirements for Heterotrophic Growth, and Reserve Substance in *Beggiatoa*

CATALDI[1] has shown that *Beggiatoa*, instead of living autotrophically on the oxidation of hydrogen sulphide, can grow heterotrophically on proteinacious substances. Faust and Wolfe[2] observed stimulation by acetate.

We found that most of our 14 strains isolated bacteria-free thrive on acetate, and some other organic salts, as the only organic nutrients, provided the necessary chemical elements are supplied. They utilize inorganic nitrogen and do not require growth substances. This appears to be the simplest medium imaginable for a chlorophyll-free organism.

Beggiatoa is much favoured by aeration. The growth is then dense enough to collect ample material for biochemical purposes. In such circumstances the cells are eventually stuffed with small spherical to oblong bodies slightly less refractive than the sulphur droplets in natural material. These bodies turned out to be poly-β-hydroxybutyric acid.

The utilization of acetate occurs with the help of isocitratase, the main enzyme of the glyoxylic acid cycle. This enzyme is produced not only when the organism lives on acetate but also when aspartate or glutamate is the only substrate.

CYTOLOGY

A Ring Chromosome in Man

THE known chromosomal abnormalities in man comprise mainly whole chromosome and segmental monosomy and trisomy. Ring chromosomes have been described in tumour stem lines[1,2] and in normal tissues following irradiation[3]. Recently a ring *X*-chromosome has been reported in a female with gonadal dysgenesis[4]. A self-perpetuating ring chromosome is now described in a mentally and physically retarded but pubertal male. A full clinical description of the case is being published elsewhere[5].

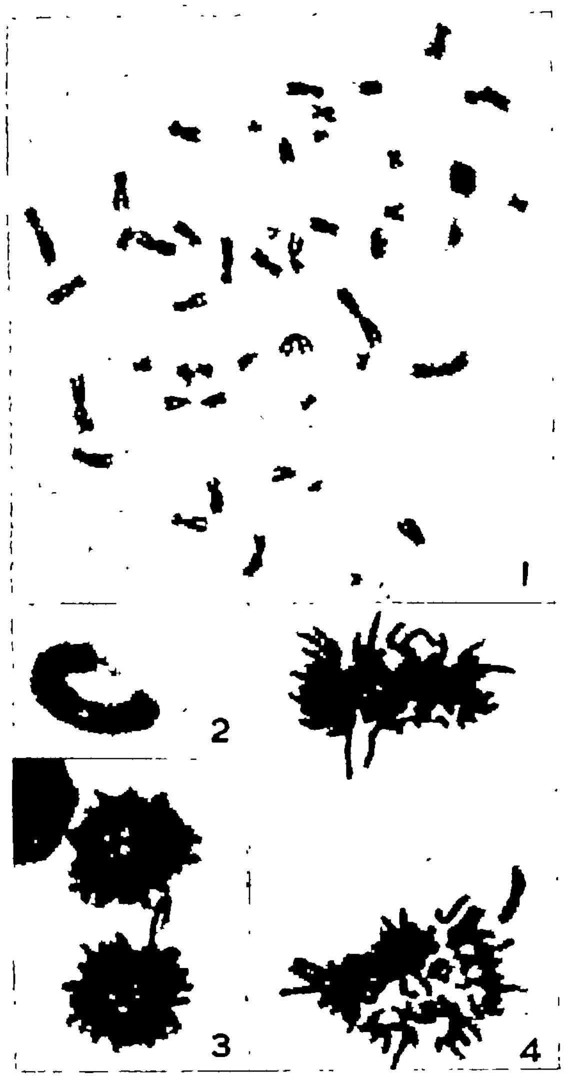
Cytological investigations have been made of cultured and uncultured peripheral blood, cultured skin tissue, and bone marrow. All mitoses in the bone marrow and most in the cultured leucocytes and skin were found to contain 45 rod chromosomes plus a monocentric ring (Fig. 1). In the cultured tissues a proportion of mitoses with 45 rod chromosomes only were observed (Table 1). Karyotype analyses indicated the absence of one member of the 6–12 chromosome group (Denver classification) in cells possessing the ring chromosome. The size of the ring was found to be consistent with the assumption that it represents this missing chromosome.

Table 1. KARYOTYPE FREQUENCIES

Tissue	Karyotypes	
	45 rods only	45 rods + ring
Cultured leucocytes	39	104
Skin	5	31
Bone marrow	0	19

The ring is generally synchronous with the rest of the chromosome complement in mitosis, but shows a significant variation in mean length (Table 2). At late prophase and at metaphase the two chromatids of the ring usually lack relational coiling (Fig. 2), and at anaphase the two daughter chromosomes separate without interlocking. In occasional anaphases interlocked or dicentric rings are present, and these may bridge the anaphase or may lag and be excluded from the daughter nuclei (Figs. 3 and 4). Conformably, micronuclei have been observed in both cultured and uncultured leucocytes.

The observed variation in the size of the ring must result from breakage and re-union of bridged dicentric or interlocked rings. Lagging and exclusion of such rings must also generate the nuclei with 45 rod chromosomes only,



Figs. 1–4. 1, Colchicine metaphase showing 46 rod chromosomes and the monocentric ring (× 1,050); 2, monocentric ring at prophase showing absence of relational coiling (× 2,300), 3, dicentric ring chromosome bridge at anaphase (× 1,300); 4, non-disjunctional interlocked rings at anaphase (× 1,300)

and the micronuclei. The absence of cells with two ring chromosomes, which would be expected from non-disjunction, may indicate either regular double exclusion or else lethality of the trisomic condition. The latter assumption is concordant with the fact that trisomy for the larger autosomes in man is unknown, and so it may be further suggested that the ring is an autosome rather than the X-chromosome.

The dicentric and interlocked rings derive from relational coiling, which must be limited to one 180° half twist or to one 360° full twist since knotted dicentrics and doubly interlocked rings have not been observed. Relational coiling in ring chromosomes has been attributed alternatively to rotation of the plane of chromosome splitting[6] or to sister chromatid breakage and re-union (mitotic sister chromatid crossing-over) combining with uniplanar chromatid replication[7,8]. In the former hypothesis breakage and re-union are necessary for free ring separation. Superficially, the behaviour of this ring chromosome favours the second hypothesis. However, such a hypothesis provides no implicit cause of breakage, whereas rotation of the plane of split could lead in a ring chromosome to torsions which would cause breakage in each mitotic cycle, allowing the relational coiling to be undone.

Table 2. Mean Relative Chromosome-Lengths (Arbitrary Units)

Chromosome	1	2	3	Ring
Mean length	18 8 ± 0·6	18 3 ± 0·6	14·8 ± 0·5	6·2 ± 0·3
Variance of log transforms	0 0103	0 0103	0·0097	0 0184

$F_{1}/_{2(47,47)} = 1\cdot06$ Non-significant

$Fr/_{3(47,47)} = 1\cdot79$ Significant at 5% level

Since the ring chromosome is present in all the tissues which have been studied, and since the cells which lack it can be accounted for by non-disjunction, the individual does not appear to be a primary mosaic. It is therefore inferred that the ring was present in the original zygote. Both the parents, however, have normal 46 chromosome karyotypes, so that the ring must have been formed at or shortly before gametogenesis in one parent. Alternative methods for its origin are: (*a*) somatic breakage and re-union, which would require two simultaneous breaks and would necessarily involve segmental deficiency; (*b*) meiotic crossing-over in a parent heterozygous for an inverted intrachromosomal translocation, such as $\frac{ABCDE.FGHIJ}{ADE.FGHBCIJ}$. Since a maternal uncle is known to have been mentally retarded and to have died in a mental institution, the second hypothesis is favoured, the mother then being the heterozygote.

The syndrome of mental and physical abnormalities shown by the individual may be a consequence of the mitotic instability of the ring chromosome and the secondary mosaicism for monosomic cells, or may be due to genic deficiency in the ring. The latter is not an obligatory assumption, since on the basis of the second hypothesis of ring formation it would result from interstitial but not from terminal translocations.

An Optically Efficient Method for observing Single Plant Cells from Shake Cultures during Growth and Division

The ease with which the individual cells of callus cultures of tissues of higher plants separate from each other has led to several successful methods of growing them singly. Muir, Hildebrandt and Riker[1] grew a single crown-gall callus cell on a piece of filter paper over a large callus of the same strain. Torrey[2] placed many separate cells around a nurse callus; some of the former divided once or more during the subsequent two weeks. Bergmann[3] made a considerable advance by utilizing a plating method for individual cells of tobacco and of bean. Of the numerous separate cells in a thin plate of agar medium, individuals were followed by time-lapse photography during their division. Optical quality of the pictures was poor due to the necessity of observation through the bottom of a Petri dish and a layer of agar. A perusal of these methods or an attempt to duplicate them makes the investigator conscious of their deficiencies; there is no possibility of observing the single cell in the first and growth is recognized only when it has formed a callus that is visible to the unaided eye, the second has most of the disadvantages of the hanging-drop, and the third suffers from poor optical quality.

In attempts to gain a cellular picture of the changes involved in the callus of *Sequoia sempervirens*[4] grown in a wide variety of media, I have worked out a method that appears to yield high optical quality and to permit prolonged observations in sterile conditions without loss of volume of the medium. The individual cells in suspension were obtained by shaking the tissue in Erlenmeyer flasks containing the standard medium without agar at 160 r.p.m. for 10 days. The observation chamber to be used on the stage of the inverted phase contrast microscope was made by grinding two half-overlapping holes 2·5 cm in diameter near the centres of glass plates 2 mm thick, 6 cm wide and 10 cm long. These plates and cover-glasses 48 mm × 60 mm in size and No. 1 in thickness were cleaned by the method of Rappaport and Bishop[5] and after drying by evaporation were sterilized at 175° C for 4 h. After cooling, an oval line of sterile Dow Corning silicone stopcock grease was placed on the cover-glass *c.* 5 mm back of the top and side margins. Cover-glass was then pressed securely on the slide so as to force a minimum of the grease into the chamber and none at all beyond the edge of the cover-glass on to the slide. Resting the slide with the open chamber up, 0·5 ml. of the suspension of individual cells was added. With some practice, it has been found possible to judge the necessary quantity of sterile liquid culture medium to be added next. Usually it amounts to about 4 ml., and brings the meniscus of the liquid to a slight bulge above the edges of the cavity. Next, a second cover-glass is prepared with the stopcock grease and pressed down over the liquid-filled cavity. A proper preparation can be considered one that has a small gas bubble trapped above the liquid and which loses no liquid from the edges of the cover-glass when the latter is pressed down, effectively sealing the contents from evaporation and entrance of micro-organisms.

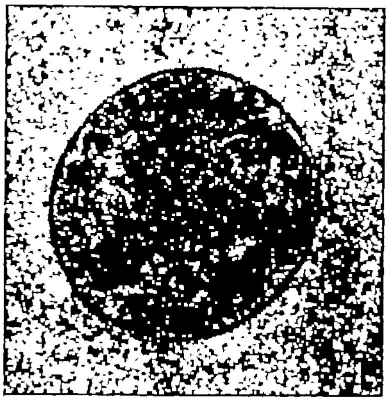

Fig. 1. Single cell of callus of *Sequoia sempervirens* resting on the lower cover slip at the time of inoculation in the observation chamber. (× *c.* 220)

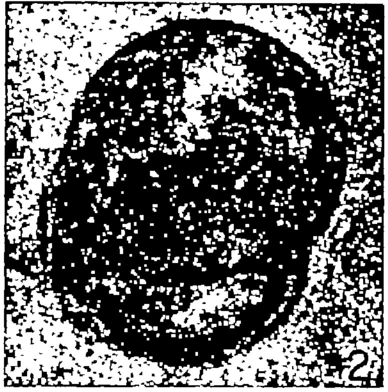

Fig. 2. The two derivative cells produced by the division of the cell of Fig. 1. The lower cell was attached to the glass surface. The division figure was produced at right-angles to the glass surface; the upper derivative cell was almost directly above the lower. (× *c.* 220)

The Dow Corning silicone stopcock grease was found ideal for the purpose outlined above. It is inert chemically, and appears to be sterile bacteriologically as it comes in the tube. Precautionarily, it was autoclaved at 120° C for 15 min.

The preparation, now containing scores of freely floating individual cells, was placed on the stage of the inverted phase-contrast microscope. All the cells rested at the bottom of the liquid on the specially cleaned glass surface of the lower cover slip and could be viewed as images of excellent optical quality through the objectives. An appropriate cell was chosen, centred in the field and time-lapse pictures at intervals of 2 min were taken. Fig. 1 shows such a cell at the time of inoculation, and Fig. 2 shows the two derivative cells 36 h later. Attachment of the cell to the glass surface had occurred prior to the division and the mitotic figure was oriented at right angles to the surface. Subsequent growth during a period of 7 days produced five additional cells all resting upon the one anchored to the cover-glass. Attachment of multicellular callus to glass surfaces was reported by Ball[6] and by Gadgil[7]. It would appear in the present work that the attachment of the single plant cell to the glass surface is comparable to that considered normal in culture of animal cells[3].

The negatives for Figs. 1 and 2 were taken through a × 20 phase objective and a × 5 ocular on to 35-mm motion picture film. This work was supported by National Science Foundation grant No. 4394.

Induction of Partial Synchrony in Mammalian Cells by Sub-culturing Procedures

THERE are many advantages of working with synchronized cell cultures and, indeed, much work has been done in this field[1]. However, the interpretation of many kinds of experiments requires either that the cultures be not synchronized, or that the investigator be aware of the possibility of inadvertent synchrony[2].

This communication reports instances of such unintentionally induced partial synchrony of human amnion[3] and kitten lung[4] cells grown in Rose chambers and examined by means of time-lapse microcinematography.

Both the medium used and general culture methods have been described[5]. Cells were removed from the glass surface of the stock culture bottle by gentle scraping with a rubber policeman, separated by passage through a 15-gauge needle, and seeded into the Rose chambers (approximate capacity, 2 ml.). In one case, *HA*36, a pre-adapted medium was used, that is, one in which cells had previously been grown for approximately 24 h. Photography began 24–30 h after seeding the chambers with 5,000–10,000 cells at *p*H 7·8 and was continued for periods of 100–122 h at 37·2 ± 0·5° C. A thermistor oiled to the coverslip of each chamber regulated the temperature by controlling a continuously variable voltage fed to an infra-red heating lamp. The chamber itself was shielded from direct infra-red rays by a strip of aluminium foil. The sensitivity of the system was such that in any given experiment the temperature of the cells varied no more

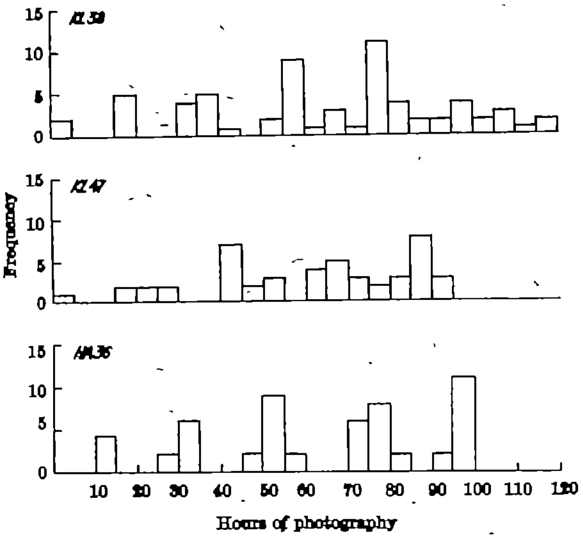

Fig. 1. Frequency of mitoses plotted as a function of time since the beginning of the photography

than 0·1°–0·2° C, although the differences between experiments might have been as great as 0·5° C due to calibration problems and changes in instrumentation.

The only mitoses recorded were those of cells which were traceable from generation to generation. Pedigree diagrams showing generation times of individual cells will be reported in detail elsewhere.

Fig. 1 is the frequency distribution which shows that peaks of mitoses were repeated for at least four cell generations. In *HA*36, synchrony was somewhat better preserved despite the fact that this was the only culture prepared with pre-adapted medium. In these experiments, we were dealing with the offspring of only a few cells in a sparsely populated chamber. To determine whether the synchrony could be due to these unique conditions, a single exploratory experiment was carried out using cells seeded on coverslips in Leighton tubes. While the results in Fig. 2 indicate a periodicity of mitoses for the first 45 h, the degree of synchrony was not great and appeared to have been soon lost.

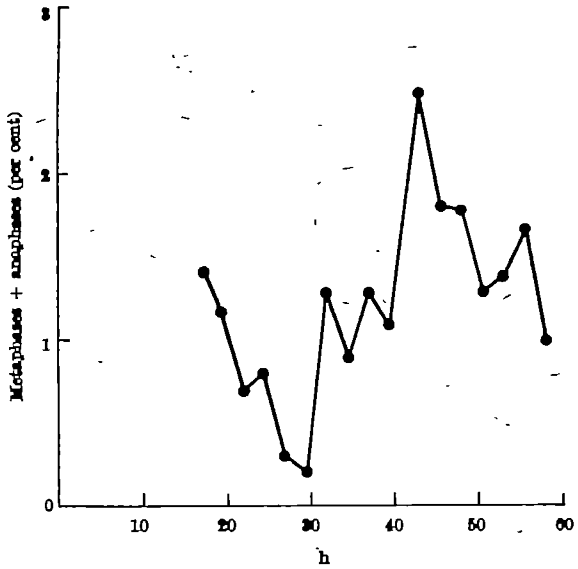

Fig. 2. Frequency of metaphases + anaphases in Leighton tube coverslip cultures of kitten lung cells as a function of age of the culture. Original inoculum: approximately 26,500 cells/ml.

The reasons for this synchrony are unknown. The experiment in which a pre-adapted medium was used appears to rule out the possibility that subculturing into fresh medium could be an only cause of synchrony. The other possible causes could be either the cooling of the cultures to room temperature during sub-culturing, although this is a gentler treatment than that deliberately used by Newton and Wildy[6] to induce synchrony, or the trauma produced by scraping the cells off the surface of the glass bottle.

GENETICS

Assortative Mating in producing New Species

Thoday and Gibson[1] have recently reported an experiment with *Drosophila* where assortative mating occurred in a small population artificially selected to remove the central portion of the distribution for number of chæta. This assortative mating was so complete that 12 generations of such selection produced two distinct lines with no overlapping.

Parker[2] reported a fertility problem with the Cornish breed of poultry. Six Cornish males, mated to a flock of 90 females of the New Hampshire breed, gave a much lower average fertility than the same flock with New Hampshire males. Repeated trials gave the same result.

Various tests finally disclosed that both sets of males were equally fertile. However, with Cornish males up to 14 per cent of the hens gave all infertile eggs, but with New Hampshire males only 2 per cent of the hens gave this result. Some of the hens were infertile in two different trials.

Since this was a flock mating it would appear that mating preference was being exercised by males and/or females and that such preference was common to all the males of the Cornish breed and/or several of the New Hampshire females.

This would seem to be further evidence of the possibilities of assortative mating in producing new species.

Balanced Polymorphism in *Dactylis glomerata* Sub-species *woronowii*

A case of balanced polymorphism, involving a recessive gene causing albinism, in *Dactylis glomerata* sub-species *judaica* has been reported by Apirion and Zohary[1]. What appears to be the same phenomenon is now reported for another diploid sub-species, *woronowii*, a seed-sample (No. 24171) of which was made available to me by the Division of Plant Industry, C.S.I.R.O., Canberra. Albino seedlings appear with a frequency of 13·5 per cent in this sample, and it may be taken that one is dealing with a recessive allele which, because of the lethality it confers in the homozygote, is present in unexpectedly high proportion. Evidently some superiority is attached to the heterozygous condition, which probably displays itself through a greater competitive ability in the seedling stage or a greater reproductive capacity when mature. However, because of the changed environmental circumstances in which the material is now being grown this selective advantage may be altered or lost. These possibilities are being investigated.

PSYCHOLOGY

Learning Deficits of Offspring after Administration of Tranquillizing Drugs to the Mothers

IN previous reports[1-4] from this laboratory, various psychotropic drugs administered to gravid rats resulted in increased neonatal mortality and altered the development and behaviour of the surviving offspring. On the basis of observations[1] that learning ability was not altered in offspring after prenatal administration of drugs that affected diencephalic centres, it was suggested that particular drugs may have a specificity of action on developing fœtal brain centres and would alter behavioural processes controlled by these centres. This communication compares three commonly used tranquillizing drugs (reserpine, chlorpromazine and meprobamate) with different pharmacological properties and sites of action, administered to gravid rats for their effect on maze learning ability of the offspring.

Subjects were 89 gravid (primiparous) albino rats of the Sprague–Dawley strain (Holtzman Co.). Breeding procedures have been described in detail elsewhere[1-4]. The drugs administered were reserpine, chlorpromazine and meprobamate. Reserpine was prepared from reserpine phosphate powder in a 1·0 per cent solution with distilled water. Chlorpromazine was prepared from chlorpromazine hydrochloride powder in a 0·1 per cent solution with distilled water. Meprobamate was prepared from meprobamate powder in a 0·5 per cent solution with distilled water heated to 80° C and cooled at room temperature to retard recrystallization. All drugs were unbuffered with *p*H in the range of 5·8–6·4. The drugs were prepared every 48 h. The daily dosages were: reserpine (0·1 mg/kg), chlorpromazine (6·0 mg/kg), and meprobamate (60·0 mg/kg). A volume control of distilled water was also administered. These daily dosages were divided in three equal amounts and injected every 8 h at 8 a.m., 4 p.m., and 12 midnight in order to maintain blood-levels. All injections were administered subcutaneously in either the right or left dorsal area with the side of injection alternated. The drugs were administered during one period of gestation on either days 5–8, 11–14, or 17–20.

Of the 690 offspring that survived through weaning (21 days of age), a random sample of at least 10 males and 10 females from pooled litters from each period of administration was selected from each of the drug and control groups. Learning ability measures were obtained from 232 animals on the Lashley III maze for an 8-day period starting at 82 days of age and after 7 days pretraining on a straight alley and acclimatization to a 23-h food deprivation schedule. The apparatus and procedure for this test have been previously described[5].

Table 1 gives the number of animals evaluated in each group on the Lashley III maze with the mean and standard deviation for the number of trials required to reach the criterion of learning. The mean score includes the criterion trials. The criterion of learning was defined as two out of three errorless trials run in 20 sec or less per trial. The score for each drug and control group is a combined score of males and females and combined periods of administration. This was done because no significant or consistent differences were found between males and females or between periods of administration. Statistical analysis among groups was done with the *t*-test. In comparing each of the drug groups to the control group, only the offspring of the meprobamate-treated mothers required significantly more trials to reach the criterion of learning. This difference is significant at the 0·01-level with a *t* score of 4·13. In comparing the drug groups between each other the meprobamate group is found to be significantly higher than the reserpine group ($t=2·30$, $P=0·05$) and the chlorpromazine group ($t=3·96$, $P=0·01$). No significant difference between the reserpine and chlorpromazine groups is noted.

Table 1. TRIALS TO CRITERION ON LASHLEY III MAZE OF OFFSPRING OF MOTHERS ADMINISTERED TRANQUILLIZERS DURING GESTATION

Group	No.	*M*	*S.D.*
Reserpine	56	10·7*	4·6
Chlorpromazine	57	9·4†	4·1
Meprobamate	60	12·7	5·0
Control	59	9·5†	3·4

Difference between this score and meprobamate is significant at the * 0·05- and † 0·01-levels respectively.

The finding that only meprobamate of the three tranquillizing drugs administered to gravid rats detrimentally altered maze learning ability of the offspring was anticipated. Meprobamate, in contrast to the other tranquillizing drugs (reserpine and chlorpromazine), is known to have a depressing effect on the cerebral cortex[6]. In this respect and in other ways, meprobamate is considered to have pharmacological properties of a barbiturate[7]. Other investigations, in which barbiturates[8] and other potent central nervous system drugs such as sodium bromide[9] and alcohol[10] were administered to gravid rats, also report deficits in the learning ability of the offspring.

Although no complete explanations are available to account for these results, several possibilities must be considered. The first possibility is that the prenatal administration of meprobamate altered the animal's physical condition and impaired its performance. Consistent and significant differences in physical condition as measured by gain in weight between the various groups were noted at all ages from weaning until the termination of the experiment with meprobamate and reserpine offspring weighing less than controls and chlorpromazine offspring weighing more than controls[3]. Although the meprobamate and reserpine offspring weighed less, they also were significantly less active on two separate activity measures[4]. If decreased activity accounted for poor performance on the Lashley III maze, then both the reserpine and meprobamate offspring should have been detrimentally affected. However, this was not the case and only the meprobamate offspring showed the learning impairment. The criterion for learning depended not only on speed of running but also on making correct responses.

A second consideration is that the learning impairment of the meprobamate offspring reflects altered development and/or function of the cerebral cortex. Whether this is a direct consequence of meprobamate on the fœtal central nervous system or whether meprobamate created metabolic changes in the gravid animal which indirectly caused alteration of the fœtal central nervous system through such mechanisms as anoxia has not been determined in the present experiment. The fact that these drugs do pass the maternal–fœtal placental barrier[11] suggests that meprobamate could have exerted a direct influence on the central nervous system of the developing fœtus.

The findings from the present investigation support the hypothesis that pharmacological agents may have a specificity of action on developing brain areas so that tranquillizing drugs such as meprobamate can produce learning deficits in offspring of mothers administered such drugs.

We acknowledge the support of the following companies for supplying the drugs used in this experiment: Ciba for

reserpine, Smith, Kline and French for chlorpromazine, and Wyeth for meprobamate.

Intermodality Transfer of Specific Discriminations in the Monkey

WE wish to report evidence that monkeys trained to discriminate between two forms using only tactual cues are affected by such experience when the same forms are presented visually with tactual cues excluded.

Six rhesus monkeys were used in two experiments. All testing was done in a Wisconsin general testing apparatus, with food reward for the correct choice of two objects presented simultaneously. Forty (non-correction) trials were given daily. All objects to be discriminated (cross, square, *S*, etc.) were cut from ¼ in. plywood, painted black, and attached to food-well covers. For visual discriminations, transparent plastic cylinders covered the objects; tactual discriminations were performed in the dark with the objects uncovered.

In the first experiment, all monkeys learned to discriminate between 11 pairs of objects, both visually and tactually. Each problem was learned to a criterion of 27 correct responses out of 30. The first pair of objects given to an animal (and the third, fifth, etc., pairs) was learned first visually and then tactually; the even-numbered pairs were learned first tactually and then visually.

Comparisons were made of average performance on tactual problems presented after visual learning of the same objects (transfer problems) with performance on those problems for which tactual learning was the initial experience with the object pair. Neither trials to criterion nor errors in the first 30 trials of each problem disclosed a significant transfer effect. Furthermore, similar analyses of visual-problem performance provided no evidence for tactual-visual transfer.

During the tactual problems animals were observed (with a snooperscope) and it was noted that only rarely did they palpate the full surface of the stimuli before making a choice. Usually some aspect of the near edge of the stimulus, or the distance of some part of it from an exposed edge of the testing board, appeared to be the effective cue; and it is well known that not all aspects of a stimulus object presented visually enter equally into the discrimination which is learned. It is possible that our subjects (and those of other experiments) did not always 'see' the same part or aspect of the object as the part that they 'felt'. Stimulus objects for the second experiment were designed so that there would be more certainty as to the nature of the discrimination being formed.

Pieces of ¼ in. plywood, ½ in. in width, and either 1 in. or 2 in. in length, were used. The wooden strips were attached to food-well covers, and were so oriented that they differed in length in the near–far dimension of the animal. Three short stimuli were made, with the near edge of the wooden strip ¼ in., 1¼ in., or 2¼ in. from the near edge of the food-well cover; two long stimuli were made, with the near edge of the strip ¼ in. or 1¼ in. from the near edge of the cover. On each trial one short and one long stimulus were presented, with balanced series determining the combination to be used and the right–left placement of the positive stimulus.

The subjects were divided randomly into two groups of three monkeys each, which received the sequences of problems shown in Table 1. The first two discriminations were run to a criterion of 38 correct out of 40 trials, plus six consecutive correct trials on each of the six combinations of stimuli. On the day after an animal reached criterion on a problem, 10 additional trials were given on that problem followed immediately by 30 trials on the next problem.

Table 1. SEQUENCES OF LENGTH DISCRIMINATIONS, AND PERFORMANCE ON TRANSFER TESTS

Group	Tactual (1) Positive stimulus	Visual Positive stimulus	Visual Errors in first 30 trials	Tactual (2) Positive stimulus	Tactual (2) Errors in first 30 trials
I	Short	Short	9	Long	28
	Short	Short	13	Long	24
	Short	Short	14	Long	16
II	Long	Short	16	Short	16
	Long	Short	18	Short	20
	Long	Short	21	Short	27
			$P < 0.05$		$P > 0.05$

Evidence for intermodality transfer is shown on the first 30 trials of the visual discrimination (Table 1). All animals that had previously learned the same discrimination tactually (Group I) made fewer errors than all animals that had had the opposite tactual discrimination ($t = 3.01$, $P < 0.05$). Furthermore, the two groups of scores are placed appropriately on either side of the chance value of 15. (The effect is apparently weak in comparison to other influences, for the groups did not differ in trials-to-criterion on the visual task nor on performance on the second tactual task, where the strong intramodal effect of the first tactual task apparently overwhelms any possible intermodal effect.)

We conclude, then, that a specific intermodality transfer effect can be demonstrated if we require that the 'same' discrimination be made in the two modalities. It can be suggested that in our first experiment there were some problems on which individual animals happened to make use of the same cues in the two modalities: each animal met criterion immediately (in the first 30 trials) more frequently on transfer problems than on non-transfer problems—for visual and tactual problems combined, or for tactual problems alone. Perhaps the one monkey of Ettlinger[1] which showed what may have been tactual-visual transfer happened to attend to the same cue in the two modalities.

In this experiment we have studied transfer between touch and vision when the same objects are presented to the two modalities. This must be distinguished from transfer between analogous auditory and visual discriminations[2], evidence for which has come primarily from an experiment[3] the results of which might possibly be explained as due to an even more general effect, the intermodality facilitation of learning sets[4]. These may prove to be three different kinds of transfer in discrimination problems, which must be studied separately.

In any event, a method for demonstrating specific intersensory transfer opens the way to investigations of the role of early sensory experience and of various neural structures in the normal development of such transfer.

These experiments were supported in part by a grant (*M*–4472) from the U.S. National Institutes of Health, while one of us (O. C. S.) was a National Science Foundation Graduate Fellow (No. 21289).

Influence of Hunger on Olfactory Acuity

A HUNGRY animal is considered to be in a state of high nervous irritability leading to a heightened level of sensory and motor excitation. As glycogen stores are depleted, blood glucose-levels decrease, circulating epinephrine rises and stimulates the reticular formation of the brain, which in turn produces cortical arousal and facilitation of motor and sensory activity, lowering the threshold for all external sensory stimuli[1]. A satiated animal, by contrast, is relaxed, disinterested in the outside world, sleepy, and consequently should have a high sensory threshold.

There are conflicting opinions on whether olfactory acuity is a reliable, reproducible index of appetite, hunger, or satiety. According to Goetzl[2], freely selected meals, as well as administration of sucrose solutions, were preceded by increased olfactory acuity and followed by decreased acuity. Janowitz and Grossman[3] were unable to duplicate Goetzl's results. Subsequent investigators, however, have reported that olfactory acuity was higher before lunch than after lunch[4]. Coffee and citral, respectively, were used by the first two investigators, whereas isoamylacetate, *n*-butanol, and oil of cloves were tested by the third. Their respective testing methods were the Elsberg blast-injection technique, sniffing odour-saturated air in an olfactorium, and sniffing from a series of test-tubes.

An olfactometer designed to deliver calculated amounts of odour in purified air, at controlled flow rates, temperatures, and humidities, and utilizing natural breathing, was used[5]. Experimental subjects consisted of University personnel, 11 males and 1 female, 30–58 years of age, selected on the basis of their proved olfactory acuity and reproducibility of judgment. Citral was found to deteriorate rapidly, changing its odorous characteristics, therefore 2-heptanone, a highly stable compound which smells like mild blue cheese, was substituted. The panel was divided into two groups which were tested alternately just before lunch (11 a.m.–12.15 p.m.) and just after lunch (1 p.m.–2.15 p.m.).

Table 1. OLFACTORY RESPONSES PRECEDING AND FOLLOWING LUNCH

Subject	Sex	No. of judgments a.m.	No. of judgments p.m.	Correct response (per cent) a.m.	Correct response (per cent) p.m.
A	M	400	480	65	70
B	M	370	350	62	75
C	M	400	490	71	71
D	M	290	420	69	75
E	M	380	380	66	80
F	M	330	490	77	72
G	M	290	190	69	73
H	F	450	420	72	72
I	M	270	260	65	67
J	M	350	490	70	76
K	M	450	470	68	74
L	M	450	440	77	80
Average		369	407	68·1	73·7

Since all the standard testing procedures had one or more serious defects, a constant stimulus method was developed which would eliminate the fatiguing effect of a strong concentration preceding a weaker one and would place each subject on an equal sensitivity basis. Ten samples were administered at each daily session. Each sample was presented for 15 sec with a 15-sec interval of pure air between subsequent presentations. The number of samples containing odour and the order of presentation were determined by chance. The concentration of odour given was slightly above threshold for each subject as determined by previous testing. Subjects were requested to indicate the presence or absence of the test compound. Over a period of 5 months, an average of 369 and 407 separate judgments was obtained from each subject before and after lunch, respectively.

As shown in Table 1, only subject *F* was more acute before lunch, subjects *C* and *H* showed no difference, whereas the remaining nine were more acute after than before lunch. The *t*-test for variance indicated the difference between morning and afternoon panels was significant at the 0·1 per cent level of probability. Thus, using an olfactometer-presentation of 2-heptanone by a constant stimulus methodology, olfactory acuity was higher after lunch than before.

A Vertical–Horizontal Illusion for Movement perceived tactually

THERE is a well-known visual illusion in which a vertical line is judged as longer than a horizontal line of the same length. The illusion also holds, though attenuated, when lines are perceived tactually, even in blind subjects[1]. This communication is concerned with a similar error which is made when speed of movement is assessed tactually, but which does not show when the judgment is made visually.

The apparatus consisted of two 6-in. drums the speed of rotation of which could be varied. One was mounted with its axis vertical, the other horizontal. The drums were covered with paper embossed by means of Braille writing equipment with a pattern of dots in triplets, 1 mm across, and with an interval of 12 mm between triplets of dots. In both experiments the subject rested his finger-tips against the dots on the surfaces of the drums as they rotated. Thus one hand was held in a vertical plane and the other horizontally.

In the first experiment, subjects were required to adjust the speed of one drum so that it appeared tactually (with eyes shut) to rotate at the speed of the other. All 12 subjects adjusted the speed so that the drum with vertical axis was objectively rotating faster. This means that the speed of the dots moving vertically past the fingers was overestimated.

The finding was tested in another way. The two drums were rotated at the same speed with dots passing the fingers at 27·5 mm/sec, and subjects were each required to make a single tactile judgment as to which drum was rotating faster (subjects were not allowed to say 'equal'). Of 24 subjects, 19 reported that the drum with horizontal axis (vertical movement) was the faster. On a χ^2 test this result is expected in less than 1 per cent of cases by chance. Another 24 subjects made the judgment visually. Thirteen reported the drum with horizontal axis as faster, 11 the drum with vertical axis. In the tactile judgments the effect did not depend on whether the dots were moving away from or towards the body, nor did it depend on handedness.

The results suggest a vertical–horizontal asymmetry in tactile perception. The most plausible explanations of visual illusions[2] are in terms of eye-movements, or configurational effects or depth perception. None of these appears to explain the present illusion.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, January 7

British Institution of Radio Engineers, Research Committee at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 2 p.m.—Symposium on "Radio and Electronics Research in Great Britain".

University College, London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5 p.m.—Prof. Harland G. Wood (U.S.A.): "The Problems of Determining Pathways of Carbohydrate Metabolism using Labelled Glucose".* (Further lecture on January 10.)

Institution of Mechanical Engineers, Steam Plant Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Testing of Modern Large Steam Generating Plant".

Royal Institute of Chemistry, London Section (joint meeting with the London Section of the Society of Chemical Industry, at the Society of Chemical Industry, 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Dr. Alexander King: "Scientific Research in Europe in Relation to Economic Development".

Tuesday, January 8

Institution of Chemical Engineers, South-Eastern Branch (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 4 p.m.—Annual General Meeting. 6 p.m.—Discussion Papers.

Institution of Electrical Engineers, Science and General Division (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. R. E. Hayes: "Cryogenics".

Institution of the Rubber Industry (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. G. F. Bloomfield: "Recent Developments in the Malayan Rubber Industry". 7 p.m.—Prof. C. E. H. Bawn, F.R.S.: "Some Aspects of Stereospecific Polymerization".

Wednesday, January 9

Society for Applied Bacteriology (in the Barnes Lecture Theatre, Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 10.30 a.m.—Winter Meeting. 2.15 p.m.—(joint meeting with the Microbiology Group of the Society of Chemical Industry)—Symposium on "Applied Aspects of Mixed Microbial Populations".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. J. C. Duckworth: "Progress and Innovation" (Peter Le Neve Foster Lecture).

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. R. V. Beavon: "The Succession and Structure East of the Glaslyn River, North Wales" (to be read by Prof. Alan Wood); Mr. N. J. Soper: "The Structure of the Rogart Igneous Complex, Sutherland".

Institution of Electrical Engineers, Power Division (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. B. J. Chalmers: "Asynchronous Performance Characteristics of Turbo-Generators".

Institution of Mechanical Engineers, Thermodynamics and Fluid Mechanics Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. D. T. Shore: "Heat Exchange in Profound Hypothermia. Heat Exchanger Design for Blood during External Circulation"; Mr. B. G. B. Lucas and Mr. S. R. Montgomery: "Engineering Aspects of Extra-corporeal Blood Circulation".

Plastics Institute (at the Wellcome Building, Euston Road, London, N.W.1), at 6.30 p.m.—Mr. W. S. Callender: "Plastics in the Bakery and Confectionery Industries".

Society of Instrument Technology, Measurement Technology Section (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. D. H. Desty: "Recent Advances in Gas Chromatography".

Women's Engineering Society (at "Hope House", 45 Great Peter Street, London, S.W.1), at 7.30 p.m.—Mr. J. M. Low: "Man-made Fibres".

Thursday, January 10

Royal Institution of Naval Architects (at 10 Upper Belgrave Street, London, S.W.1), at 4.45 p.m.—Mr. J. W. English: "Hydrodynamic Factors Affecting the Design and Performance of Lateral Thrust Units for Ships".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. M. Waldram: "Some Engineering Aspects of Lighting" (Fifth Hunter Memorial Lecture).

Radar and Electronics Association (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 7 p.m.—Mr. C. C. Martin: "Integrating Electronics in Missile and Space Systems".

Friday, January 11

Biochemical Society (at the National Institute for Research in Dairying, Shinfield, Reading), at 10 a.m.—Scientific Papers.

Institution of Mechanical Engineers, Thermodynamics and Fluid Mechanics Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "The Effect of Installation on Pump Performance".

Saturday, January 12

Association of Clinical Biochemists, and the Biochemical Society (in the Physics Department, The University, Reading), at 9.40 a.m.—Symposium on "Chromatography in Clinical Biochemistry. Standard Methods and Recent Advances".

Monday, January 14

Society of Chemical Industry, Pesticides Group (at 14 Belgrave Square, London, S.W.1), at 4.30 p.m.—Mr. J. M. Winchester and Mr. R. Pearson: "Development of Packages for Pesticides".

British Society for the Philosophy of Science (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. R. B. Braithwaite: "Believing (as Opposed to Considering) Natural Laws".

Institution of Electrical Engineers, Science and General Division P.G.86 (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. J. Thomson: "Modern Transducers with an Electrical Output".

University of London (in the Eugenics Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. Paul Turan (University of Budapest): "Analysis and Diophantine Approximation".* (Further lectures on January 15 and 16.)

Institution of Mechanical Engineers, Lubrication and Wear Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Oil Mist Lubrication".

Monday, January 14—Thursday, January 17

Institute of Physics and the Physical Society (in the Old and New Halls of the Royal Horticultural Society, Vincent Square, London, S.W.1)—Annual Exhibition.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer and a Lecturer in Applied Mathematics—The Registrar, The University, Nottingham (January 12).

Assistant Plant Pathologist (with an honours degree in botany and preferably postgraduate experience), for duties which will include general advisory work in plant pathology, and opportunities exist for research work—The Secretary, School of Agriculture, West Mains Road, Edinburgh (January 15).

Principal Lecturer in Statistics; and a Lecturer in Mathematics—The Staff Officer, College of Advanced Technology, Gosta Green, Birmingham 4 (January 15).

Lecturer (with training in mathematics and some experience in genetics, not necessarily in the human field) in Human Genetics in the Faculty of Medicine, University of New South Wales—The Agent-General for New South Wales, 56–57 Strand, London, W.C.2; and The Appointments Section, University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (January 18).

Analytical Chemist (Experimental Officer) (with a degree or H.N.C. or Diploma in Technology in Chemistry, with previous experience) in the Department of Mineralogy, for the analysis of minerals, rocks and meteorites, and research into analytical methods—The Secretary, British Museum (Natural History), Cromwell Road, London, S.W.7 (January 21).

Lecturer in the Department of Mechanical Engineering—The Registrar, The University, Liverpool, quoting Ref. CV/230 (January 26).

Lecturer (with experience in general virology or in allied fields such as biochemistry, microbiology or cytology) in Virology—The Secretary of University Court, The University, Glasgow (January 30).

Lecturer (with special interest in one or more of the following fields soils, conservation, geomorphology) in Geography—The Registrar, University College, Gower Street, London, W.C.1 (January 30)

Assistant Lecturers or Lecturers (3) (with good academic qualifications in pure or applied mathematics or in mathematical statistics) in the Mathematics Department—The Registrar, The University, Hull (January 31).

Senior Lecturer or Lecturer (with an honours or higher degree or other approved higher qualifications, and preferably with teaching experience) in Mathematics at the South Australian Institute of Technology, Adelaide—The Agent-General for South Australia, 50 Strand, London, W.C.2 (January 31).

Reader in Analytical Chemistry at Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 6).

Chair of Biochemistry at the Royal Free Hospital School of Medicine—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 7).

Lecturer or Senior Lecturer (with special qualifications in the teaching of science) in Education at the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, February 8).

Reader in Physics—The Acting Deputy Registrar, University Office (University of Durham), 1A Kensington Terrace, Newcastle upon Tyne 2 (February 11).

Chair of Geography at Fourah Bay College (The University College of Sierra Leone)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (February 15).

Assistant Lecturer or Lecturer in Inorganic Chemistry—The Secretary, The Royal College of Science and Technology, George Street, Glasgow, C.1 (February 15).

Assistant (preferably with an interest in the biochemistry of micro-organisms) in Biochemistry—The Secretary of University Court, The University, Glasgow (February 15).

Chamber of Mines Chair of Mining Engineering in the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, February 15).

Lecturer (graduate of a British Commonwealth University or of equivalent status, preferably a Corporate Member of the Institution of Mechanical Engineers, and with teaching experience at university-level) in Mechanical Engineering at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Hong Kong and London, February 15).

Lecturer/Senior Lecturer in Biology in the Department of Botany, University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, February 15).

Lecturer (preferably with interests in the field of political philosophy) in Philosophy at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, February 24).

Chair of Philosophy—The Registrar, University of East Anglia, Earlham Hall, Norwich, NOR 05G (March 30).

LECTURER IN EXPERIMENTAL PHYSICS—The Secretary, University College, Cork, Republic of Ireland (March 30).

ASSISTANT or ASSOCIATE PROFESSOR (with a Ph.D. in pharmaceutical or medicinal chemistry) IN THE FACULTY OF PHARMACY, to teach undergraduate courses, conduct research and develop a graduate programme—The Dean, Faculty of Pharmacy, University of British Columbia, Vancouver, B.C., Canada.

DIRECTOR (with suitable academic qualifications, and industrial and research experience) OF STUDIES IN THE DEPARTMENT OF TEXTILE INDUSTRIES—The Registrar, Bradford Institute of Technology, Bradford 7.

EDITORIAL ASSISTANT (with physics and/or mathematics to degree standard, and an interest in scientific publication), for work which will include the preparation of mathematical and scientific material for publication—The Editor and Deputy Secretary, The Institute of Physics and The Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7.

NEMATOLOGIST (male, with an honours degree in zoology or entomology, and at least one year's postgraduate training or experience, preferably in the study of nematodes) in the Ministry of Agriculture, Uganda, to undertake a survey of the occurrence of harmful nematodes on crops; to develop techniques for testing host reactions and for controlling nematodes of economic importance—The Director of Recruitment, Department of Technical Co-operation, Great Smith Street, London, S.W.1, quoting T/RC. 213/153/07.

ORGANIC CHEMIST (with a Ph.D. degree), for research in synthesis and reactions of organic sulphur compounds—The Professor of Chemistry, Box 1507, Substation B, Vanderbilt University, Nashville 5, Tennessee, U.S.A.

POSTDOCTORAL FELLOW IN INORGANIC CHEMISTRY, for work which will involve the preparation of inorganic polymers, and the investigation of their structure and degradation by various physical methods—The Professor of Chemistry, Westfield College (University of London), Hampstead, London, N.W.3.

POSTDOCTORAL RESEARCH FELLOWS IN THEORETICAL PHYSICS—L. H. H. Trainor, Physics Department, University of Alberta, Edmonton, Canada.

SOIL SURVEYOR (aged 23–45, with a good honours degree in chemistry, botany, geology or agriculture, and preferably some postgraduate experience of soil survey work) in the Ministry of Agriculture, Kenya, to carry out, as a member of a team, the surveying, classifying and mapping of soils for land use purposes—The Director of Recruitment, Department of Technical Co-operation, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting Ref. C1/RC.213/80/013.

TECHNICAL ASSISTANT (with a G.C.E. "A" level in chemistry and an "A" level in mathematics, physics or biology), for work on biochemical analyses—The Secretary, Institute of Cancer Research, Royal Cancer Hospital, 34 Summer Place, London, S.W.7, quoting Ref. 301/B/120.

TECHNICIAN or JUNIOR TECHNICIAN IN THE DERMO-PATHOLOGY LABORATORY at St. George's Hospital, Tooting Grove—The Secretary, Pathology Department, St. George's Hospital Medical School, Hyde Park Corner, London, S.W.1.

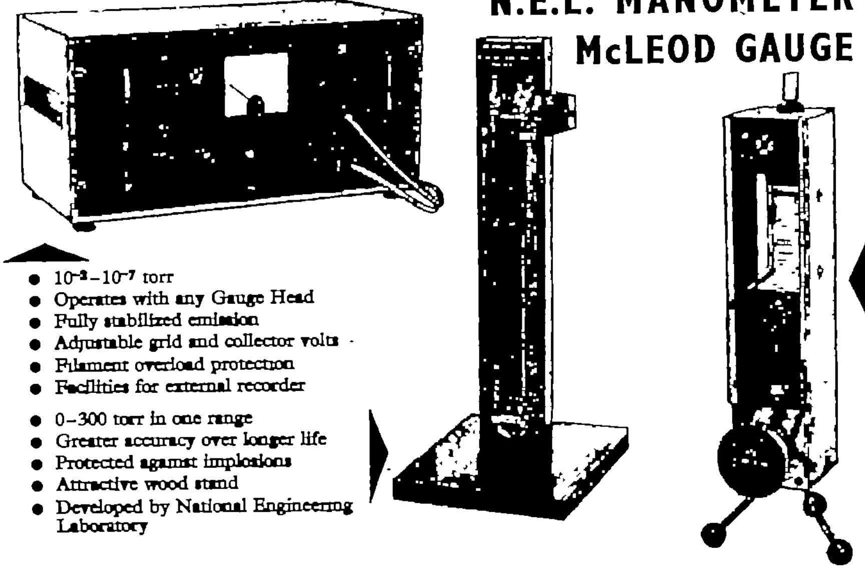
IONIZATION GAUGE CONTROL UNIT
N.E.L. MANOMETER
McLEOD GAUGE

3 NEW GAUGES *for the* VACUUM ENGINEER



- 10^{-3}–10^{-7} torr
- Operates with any Gauge Head
- Fully stabilized emission
- Adjustable grid and collector volts
- Filament overload protection
- Facilities for external recorder

- 0–300 torr in one range
- Greater accuracy over longer life
- Protected against implosions
- Attractive wood stand
- Developed by National Engineering Laboratory

- 150–.0001 torr in 3 ranges
- Compact—only 16" high
- Single hand operation
- Interchangeable heads
- No auxiliary pump required
- Robust industrial finish

We are continually developing new instruments for the measurement of vacuum. When you have a vacuum measuring problem, tell us about it—we may already be able to gauge it for you.

CHURCH BANK WORKS, CHURCH, Nr. ACCRINGTON, LANCASHIRE

Telephone: Accrington 35611-2

£500 A YEAR TAX FREE FOR YOUR FAMILY

The Equitable offers you a special plan to protect your family's future at the lowest possible cost. Should you die within a period of 20 years your dependants will receive £500 a year tax free for the balance of the period.

You only pay premiums for 15 years and if you are 29 now the cost is as little as £18.5.0. a year—about 7/- a week. The premiums for larger benefits are in proportion.

The Equitable offers attractive terms because it has no shareholders to take any part of the profits and pays no commission for the introduction of business.

THE EQUITABLE

FOR A BETTER DEAL

The Equitable Life Assurance Society,
19, Coleman Street, London, E.C.2.
Please send me full details of the 'Income for Dependants' Policy.

BARB PLUGS AND SOCKETS

The Oxley plugs and sockets are rapidly assembled connectors of outstanding electrical and mechanical characteristics, the design of the bush making maximum use of the elastic and insulating properties of polytetrafluoroethylene.
The socket tube is a one-piece component, heavily silver-plated (with an optional gold flash) slit longitudinally to exploit the elastic properties of the insulating bush, so providing the necessary retention of the plug under the most arduous conditions.
To fit ·156" dia. chassis hole.
Both plugs and sockets supplied coloured: Black, Brown, Red, Orange, Yellow, Green, Blue, Violet, Grey, and White. Packed in sealed packets of 100.
Further details supplied on request.

OXLEY

OXLEY DEVELOPMENTS CO. LTD., ULVERSTON, LANCS

CLASSIFIED ADVERTISEMENTS are charged at 12s. for the first line and 6s. per line thereafter. Lines in capitals or containing words in capitals 12s. per line. Semi-displayed £4 16s. per single column inch. Colour (orange) £15 extra. 1s. is charged for the re-direction of replies to advertisements with a box number.

ADVERTISEMENTS SHOULD BE ADDRESSED TO: T. G. Scott and Son, Limited, 1 Clement's Inn, Strand, London, W.C.2. Telephone: HOLborn 4743. Telegrams. Textualist, Estrand, London.

APPOINTMENTS VACANT

NATIONAL RESEARCH COUNCIL
POSTDOCTORAL FELLOWSHIPS

Two Postdoctoral Fellowships of the Canadian National Research Council will be tenable at Laval University for the 1963–64 Exercise in the fields of Chemical Engineering. (Chemical Reactor Dynamics. Parameters in Mixing: Transfer Functions. Transport Phenomena. Applied Mathematics; Analogue and Digital Computers). Physics. (Theoretical Nuclear Physics; Atomic and Molecular Ion Beams; Instrumental Optics, Micro-wave Diffraction, Van de Graaff work.) Stipend is $4,000 for single Fellows and $5,000 for married Fellows plus allowance towards cost of travel.

Applicants may write directly to Laval University, or to: The Awards Officer, National Research Council, Ottawa 2, Canada. Closing date: January 15, 1963.

McMASTER UNIVERSITY
POSTDOCTORAL FELLOWSHIPS IN PHYSICS

Applications are invited for National Research Council and other Postdoctoral Fellowships, tenable in the Department of Physics, McMaster University. Successful applicants may choose to work full-time on their research or to supplement their research with a modest amount of lecturing.

Inquiries and applications should be addressed to Professor M. W. Johns, Chairman, Department of Physics, McMaster University, Hamilton, Ontario, Canada.

FOURAH BAY COLLEGE
THE UNIVERSITY COLLEGE OF SIERRA LEONE

Applications are invited for the

(a) Chair of Chemistry
(b) Chair of Zoology
(c) Chair of Botany
(d) Chair of Geography

The tenure of these new Chairs can be permanent to the age of retirement but the College would consider an appointment on secondment for a limited period, e.g., five years.

Salary, £2,850 per annum; F.S.S.U., car allowance £150 per annum; family allowance £100 per child per annum (maximum £300); outfit allowance £60; annual leave; paid passages on appointment, on biennial leave and normal termination; part-furnished accommodation at very reasonable rent. Car purchase loans negotiated. There are generous funds allocated for research, equipment and travel to conferences.

Applicants whose present salary exceeds the basic salary advertised may be considered under a special arrangement.

There is provision for a certain number of research fellows and research assistants if necessary. The College has been taking the B.A. and B.Sc. general degrees of Durham University but will now commence honours courses.

The Nuffield Foundation has recently granted the College the sum of £18,000 for the development of marine biology. There is a well-equipped station available.

There are new laboratories fully staffed and with skilled senior supervisory technicians in charge.

Detailed applications (six copies), naming three referees, by February 15, 1963, to the Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1, from whom further particulars may be obtained.

AUSTRALIA
COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION
DIVISION OF SOILS
SOIL MICROBIOLOGISTS

Applications are invited for appointment to a position of Soil Microbiologist at the Division's Soil Fertility Group in the Cunningham Laboratory, St. Lucia, Brisbane.

The Soil Fertility Group in Brisbane contains workers from the Division of Soils and the Division of Tropical Pastures, and is studying basic aspects of nitrogen transformations in the soil/plant system, with reference to nitrogen balance data, N cycles in soil under pasture, and the effects of either field or fertilizer nitrogen on the distribution of this element in the various components of the system. Certain aspects of this project, which concern simultaneous mineralization-immobilization reactions in soils growing perennial grasses fertilized with nitrogen have been studied in preliminary experiments, but a soil microbiologist is required to amplify this aspect of the programme in some detail.

The group has good facilities for research, including a mass spectrometer for isotope assay, and ready access to equipment possessed by other groups in the Cunningham Laboratory is also possible; this equipment includes facilities for radioactive counting and an automatic amino-acid analyzer.

The appointee will be required to undertake research in transformation of nitrogen in tropical soils under pasture or crop and the decomposition of carbonaceous materials under these conditions.

Applicants should possess at least an honours degree in Science, Agricultural Science or Rural Science and should have had research experience in microbiology to or beyond the Ph.D. level or an equivalent training and preferably in applied microbiology research with soils

SALARY: Dependent upon qualifications and experience within the salary ranges:

£A1,541 to £A2,296 per annum or £A2,426 to £A2,751 per annum.

Promotion within C.S.I.R.O. is by merit and may ultimately go beyond the upper limit of the scale within which the original appointment is made

Fares paid for the appointee and his dependent family and return fares to point of origin will also be paid for an appointee who by arrangement accepts appointment for a fixed term. Further particulars supplied on application to:

Mr. P. F. Butler, Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2,

to whom applications (quoting Appointment No. 270/254) should be addressed by February 2, 1963

ARTHUR D. LITTLE RESEARCH INSTITUTE

This rapidly expanding Institute, which is situated in rural surroundings six miles from the centre of Edinburgh, offers a number of permanent and interesting posts in long-term research.

PHYSICAL CHEMISTS and PHYSICISTS

(a) to join a newly-formed group working on the electrical behaviour of organic and inorganic materials; (b) to study the effect of light on polymers.

ORGANIC CHEMISTS

preferably with research experience either in the field of aliphatic or heterocyclic chemistry, or with a knowledge of textile finishing treatments.

There are vacancies at both senior and junior levels. The posts are superannuated and offer good prospects with salaries according to qualifications. The Institute operates a five-day week and has canteen facilities

Applications, with full particulars of qualifications and experience to:

THE DIRECTOR,
ARTHUR D. LITTLE RESEARCH INSTITUTE,
INVERESK GATE, MUSSELBURGH, MIDLOTHIAN.

DALHOUSIE UNIVERSITY
HALIFAX, CANADA
BIOLOGY

Applications are invited for three positions in the Department of Biology. Appointments will be made at a rank and salary appropriate to teaching and research experience. For a recent Ph.D. the starting salary will not be less than $7,000.

Radiation Biologist to conduct research on some aspect of the effect of ionizing radiations on living material. Animal or microbial genetics, embryology or cellular physiology would be appropriate fields.

Zoologist working in ecology, population studies, behaviour or one of the fields mentioned above.

Aquatic or Experimental Biologist to undertake research on the productivity of natural waters.

Inquiries are also invited about post doctoral fellowships and opportunities for graduate study. Address correspondence to the head of the department.

QUEEN'S UNIVERSITY
KINGSTON, ONTARIO, CANADA
ASTROPHYSICIST

A position is open for an Astrophysicist to take charge of a new 15-inch reflector with photoelectric and spectrographic attachments, to teach, and to undertake a research programme in close relation with an active radio astronomy group based in the Departments of Physics, Electrical Engineering, and Mathematics. Teaching duties will include a course in astronomy to undergraduates and a course in astrophysics to postgraduates. Appointment will date from September 1, 1963, and can become permanent after two years. Salary and rank will depend upon qualifications which should include a Ph.D. degree and some observatory experience Appointment will be at the rank of Assistant or Associate Professor and within the initial salary range $7,000 to $10,000 per annum.

Applications and inquiries, now invited, should be addressed to the Head of the Department of Physics.

SCIENCE AND PRESSURE GROUP POLITICS

THE debate in the House of Lords on the introduction of commercial broadcasting, opened on May 9 by rd Reith, centred largely on the disclosure of the work a political pressure group for the introduction of com- ercial broadcasting given in a book, *Pressure Group*, by of. H. H. Wilson, of Princeton University, published June 1961. It was in view of the disclosures in this ok of methods alleged to be used to secure the intro- uction of commercial broadcasting ten years ago that ncern was expressed in the House of Lords as to attempts discredit in advance the report of the Pilkington Com- ittee and, in particular, to commit local broadcasting commercial use. It was not, of course, argued in the bate that pressure groups are not a normal part of our litical life, but there was some divergence of opinion as the scale and nature of their use, and some support as forthcoming for an inquiry. More especially was this pressed, as Lord Taylor put it, in respect of secret essure groups, which, without clearly identified mem- rs and objects, working underground and out of sight, e a menace to society.

The Lord Chancellor did not reply to Lord Taylor's ecific inquiry on this point, and while the debate con- asted Prof. Wilson's book unfavourably with Dr. B. aulu's *British Broadcasting in Transition*, it did little resolve the doubts which had been expressed or the nxiety with which the Pilkington Committee's report as then awaited. When on July 31 that report was st discussed in the House of Commons, the Postmaster- eneral, Mr. R. Bevins, emphasized with all the force he uld command that the Government had not been fluenced in any of these matters by any pressures or bbies, whatever their nature, nor would the Govern- ent be in taking future decisions. Mr. Bevins was eaking in support of a motion asking the House to take ote of the Government's White Paper on the report of e Committee on Broadcasting.

Nevertheless, there are aspects of this question of essure groups with which the scientist and other pro- ssional men and women are very much concerned. This as brought out by J. B. Sanderson as illustrated by the ork of the National Society for Clean Air, and more nerally is well indicated by Prof. J. D. B. Miller in his ok *The Nature of Politics* (see *Nature*, 196, 301; 1962). ithout using the term, Prof. Miller showed how institu- ons are concerned with the conflict of interests which overnments have to face, the way in which professional stitutions bring diversity and the limits within which eir influence is exerted. This is brought out even more early in an earlier book by Prof. H. Eckstein in hich, under the title *Pressure Group Politics**, he amines the way in which one important professional ody has functioned in the defence of its members as ell as of its conception of the public interest.

The British Medical Association may not have been e best example to choose for an examination of what is sentially a study of the function and locus of power nd influence in a democracy. That Association is scarcely typical professional organization. but the example serves well enough to illustrate both the character and the limits of the influence which professional bodies can exert on public policy. Moreover, Prof. Eckstein refers freely to the study of the professions by Sir Alexander Carr-Saunders and P. A. Wilson a generation ago, and much in this book endorses the soundness of their conclusions.

From the point of view of the professional man generally, the most significant chapters in the book are those which examine the framework within which pressure groups function in Britain's society and which discuss their significance in politics. Prof. Eckstein points out that the formation and activities of pressure groups are determined by the interaction of the structure, activities and attitude of Government itself, and that the growing extent of Government influence in the Welfare State has inevitably led to an increase in the number of active or potential groups. Government decisions have a direct interest on the activities and well-being of more and more groups, professional and otherwise, and this has led them, sometimes reluctantly, to interest themselves as such in politics. So far as scientists and technologists are concerned, it is the counterpart of the increasing extent to which scientific and technical considerations are of dominant importance in determining public policy.

It is thus unfortunate that the term 'pressure group' has acquired some sinister significance, for any abuse of the process does not alter the fact that such groups are an essential feature of the process by which, in the modern democratic State, those with expert and professional knowledge and skill are able to make their full contribution to public policy. We cannot wisely rely on that contribution being made solely through those engaged, for example, in the Scientific Civil Service, quite apart from the persistence of the view that the expert should be on 'top' and not on 'tap'. How a group exerts its influence is determined largely by the structure of the Government itself and the way in which decisions on policy are made. It is also determined by the organization of the group itself, and even more is this true of the effectiveness with which the group is able to influence Government decisions.

What emerges particularly from Prof. Eckstein's study is the desirability of professional organizations looking afresh at their own internal organization, not simply from the point of view of the defence of their own professional interests and the maintenance of professional standards of practice and competence, but more especially from the wider point of view of the appropriateness of that organization to serve the public interest by putting fully at the disposal of the State the collective knowledge and experience of its members. It is not to be forgotten, as well appears in this study of the British Medical Association, that professional experience and knowledge may also be made available to the Government in many informal ways. That, as for example the report of the Zuckerman Committee indicated, is in part a matter of appropriate staffing policy and sound administration. However, more critical and creative thought about the structure of professional bodies and the way in which they can make effective expert representations on matters of public policy is as desirable from the point of view of the public welfare as it is from that of the professional bodies themselves.

---

* *Pressure Group Politics: The Case of the British Medical Association.* y Harry Eckstein. Pp. 168. (London: George Allen and Unwin, Ltd., 60.) 16s. net.

This could undoubtedly go far to eliminate any fear that such professional bodies may exert any unwholesome or undesirable influence on public affairs; it is all to the good that there should be free and widespread public discussion of this general question. Not all pressure groups are as responsible as professional associations, and while the existence of pressure groups is no new phenomenon and can easily be illustrated from the nineteenth century, there is undoubtedly growing awareness and concern over the activities of local and political pressure groups. With the widening influence of the Government over the economy, such activities are likely to increase. What is desirable is that the nature of those activities should be clearly understood and the point at which their legitimacy is open to question should be widely recognized. Awareness is, in fact, probably the best safeguard against the abuse of practices which are probably unavoidable, but are undesirable as such only when they are abused or become the accepted mean.

This is the more important because the methods now sometimes used are open to criticism. It will be noted that Prof. Eckstein, like Prof. J. B. Miller, comments that the point at which pressure is exerted is increasingly the administration. "In the age of big administration and crowded legislative time-tables," he writes, "interventions by voluntary organizations are also the chief control over the executive, far more thorough and efficient than question time and adjournment debates in Parliament." Only after failure does a pressure group try Parliament, although often enough it may set out to try to create a climate of opinion favourable to its purpose.

Clearly it is undesirable that Parliament should be by-passed or ignored, though the British Parliamentary organization is not well-adapted to the widening range of its responsibilities. There is, in fact, little direct representation in Parliament of interests which find typical expression in pressure groups, and if major professional and other interests were authoritatively represented at Westminster there might be less danger of abuse. Certainly there should be a more general public understanding of the contribution which professional bodies could bring to bear on particular public issues. As Prof. Eckstein has shown, pressure groups of the professional type can contribute usefully in the formulation and administration of specific policies. Moreover, they constantly define opinion for Government, and on a level on which political parties rarely touch.

There is thus substantial evidence that pressure groups have a definite contribution to make in a democratic system where political parties sometimes fail simultaneously to provide efficient decision-makers and represent accurately opinions. Representative organizations such as professional associations supplement the party system with alternative organizations which can influence decisions without affecting the position of the decision-makers—this, as Prof. Eckstein argues, is probably their pre-eminent function in an effective democratic system. It is worth further consideration, especially by professional bodies of scientists and technologists, how best that function can be discharged.

This is not, of course, the only way in which professional bodies can perform a social function. As Prof. Eckstein also shows in his book, the difficulties of the British Medical Association in regard to the National Health Service arise in part out of the transformation of the profession from one in which the majority of members were self-employed or in independent practice to one in which they are mainly employed by the State. Mo classes of scientists and technologists have indeed alway been salaried employees, and this has from time to tim led to difficulties over professional responsibilities an standards and to the formation of bodies registered a 'Trade Unions' for the defence of their economic interest as, for example, the Association of Scientific Workers an the British Association of Chemists. By and large, thos difficulties, however, do not appear to have been considerable and, so far as public policy is concerned, it seem to have been immaterial whether representations ar made by these latter bodies or by the chartered institutions and qualifying bodies. Each seems to have it specific place and function, though, so far as industry i concerned, the bodies with economic responsibilities unde the Trade Unions Acts may be in the stronger position.

Nevertheless, this aspect of professional organization i nothing like as important—at least from the public poin of view—as Prof. W. Kornhauser suggests in a recen book†. In both this book and in a subsequent article "Strains and Accommodations in Industrial Researc Organizations in the United States", published in th autumn 1962 issue of *Minerva*, Prof. Kornhauser seems t exaggerate the stresses and clashes between professiona interests and standards and industrial objectives an purposes—in any event so far as British industry is concerned. Molehills sometimes become mountains, but, o the other hand, the real difficulties and problems of th structure and place of professional organizations in th technological society in which we live are virtuall ignored.

Both Prof. Kornhauser's book and his article are essentially on the management and control of research and perhaps because he seems to be almost obsessed with th idea that research is the only possible or legitimat occupation for a scientist, Prof. Kornhauser's book even o that theme is scarcely as illuminating as the Zuckerma report. Besides his narrow conception of the vocation o a scientist he shows no clear conception of the limits o professional competence. The admission that th diffusion of scientists and technologists throughout a enterprise with an appropriate organizational structure may diminish what he regards as the inevitabl tension between the primary functions of a professiona organization and the purposes of an industrial enterpris is as near as he gets to any recognition of the need fo a wide understanding in society as a whole and in it industrial units of the nature of scientific activity.

It will thus be seen that Prof. Kornhauser's book i disappointing—this is the more unfortunate in that th respective functions of the learned and scientific society and of the professional association have acquired a new significance and importance to-day for reasons which Prof Miller and Prof. Eckstein have made plain. That th influence of the professional body, on Prof. Kornhauser' evidence, is declining in the United States, and that in Britain the scientific society finds great difficulty in recruiting a reasonable membership from scientists and technologists in industry are beside the point. Both the scientific society and the professional institution have an essential place and an important function to perform among the various means by which expert knowledge is placed at the service of the community and given its full weight in executive decisions on public policy. It is not a healthy sign if the members of a particular profession are reluctant to support their professional institutions which are responsible for the maintenance of professional standards of acceptance or the diffusion of knowledge of advances in that field of knowledge. Neither is it healthy if these institutions are unable, for any reason, to place effectively before the appropriate authority at any level up to the Cabinet itself, as may be necessary, the considered views of their members on questions of public policy in which they have special knowledge. There is more evidence than is discussed by either Prof. Eckstein or Prof. Kornhauser that the time is ripe for a critical review of the structure and functioning of professional institutions in general and of the ways in which they can to-day most effectively and appropriately put their special knowledge and skill at the disposal of the community. Few aspects of this wide problem of power and influence are more important to-day, and once again the question of effective communication is at the root of the whole problem.

---

† *Scientists in Industry: Conflict and Accommodation*. By Prof. William Kornhauser, with the assistance of Warren O. Hagstrom. Pp. xii + 230 (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1962.) 48s.

MOLECULAR BIOLOGY AND CANCER RESEARCH

The Molecular Basis of Neoplasia

A Collection of papers presented at the Fifteenth Annual Symposium on Fundamental Cancer Research, 1961. Pp. ix+614. (Austin: University of Texas Press, 1962. Published for the University of Texas M. D. Anderson Hospital and Tumor Institute.) 10.50 dollars.

THIS remarkable book illustrates the striking way in which molecular biology has recently advanced our understanding of fundamental biological processes. That it is a report of the fifteenth annual symposium on "Fundamental Cancer Research" held at the University of Texas shows the importance of understanding biology at the molecular level for gaining insight into the phenomenon of cancer. The volume consists of thirty-four detailed lectures, all beginning with an extensive general introduction which states the problem and is invaluable to the reader who works in a different field. Most articles are by biochemists or biophysicists: but towards the end of the book materials and methods become more complex, and it is often the biologist, particularly the geneticist, who interprets the findings of the biochemist.

The first lectures deal with the building blocks of nucleoproteins and enzymes, starting with the nucleic acids. The enzymatic synthesis of artificial nucleic acids, their denaturation and the restoration of the double helix helps in the understanding of the properties of natural nucleic acids. This is particularly important in view of the fact that an analytical method for determining nucleotide sequences in natural nucleic acids is still missing. In the next group of lectures, which deal with nucleic acid and proteins, we read how analysis in chemical terms of the action of alkylating agents and some other mutagens has become possible. Furthermore, man can cheat growing cells by feeding them halogenated, instead of normal, purine and pyrimidine bases. The increased sensitivity to radiation of cells grown under these conditions finds a chemical explanation, and may one day find clinical application. Lectures on proteins in viruses and in cell nuclei, on the functional role of these proteins and their possible importance in cancer, precede chapters on conformation and on substructure of certain well-analysed protein molecules.

The second part of the book deals with more complex matters, namely, with the control of synthetic processes. The past years have brought fascinating discoveries of homoeostatic mechanisms at the enzyme level able to function in cell-free systems, inhibition being exerted either on the action or, in other instances, on the synthesis of the enzyme. Here again, biochemical progress owes much to the geneticist's techniques, the suppressor genes for example giving an explanation for enzyme induction through loss of a normal suppressing mechanism. The idea that some cancer cells may have lost a suppressor gene is suggestive indeed. Feed-back control of enzyme concentrations, first discovered in micro-organisms, has now also been found in vertebrates. The last lectures deal with the ribosomes, the vital organs for protein synthesis both in cytoplasm and cell nuclei. The precise way in which they obtain and transmit their information is still obscure, and represents one of the most debated questions of the present time.

The book is well produced, and should be of value not only to the specialist but also to anybody interested in recent advances in fundamental biology. MARTHE VOGT

BIOCHEMICAL LABORATORY TECHNIQUES

Methods of Biochemical Analysis

Vol. 9. Edited by Prof. David Glick. Pp. ix+452. (New York and London: Interscience Publishers, a division of John Wiley and Sons, Inc., 1962.) 109s.

A Laboratory Manual of Analytical Methods of Protein Chemistry (including Polypeptides)

Edited by P. Alexander and R. J. Block. Vol. 3: Determination of the Size and Shape of Protein Molecules. Pp. x+286. (London and New York: Pergamon Press, 1961.) 50s. net.

METHODS of Biochemical Analysis (Volume 9) offers the customary diverse collection of topics. Only the first two chapters on deoxyribo- and ribo-nucleases are related, and these deal with the various methods available for the assay of these enzymes. A discussion of plant hormones is mainly devoted to the extraction, purification and assay of auxins, but other plant-growth regulators, such as the gibberellins and ascorbigen, receive mention. An account of the analysis of adrenal steroids in blood by countercurrent distribution is, in my own opinion, tedious to read and overburdened with detail. In a concise survey of techniques for column electrophoresis in granular media, the authors critically consider the relative merits of various inert supports. The description of the spectrophotometry of opaque biological materials by reflexion methods is complementary to that for translucent materials in Volume 7. The remaining half of the book is devoted to magnetic resonance spectroscopy. A theoretical treatment of magnetic resonance and spectral characteristics is followed by sections on experimental techniques and biochemical applications of nuclear magnetic resonance and electron-spin resonance spectroscopy. Many biochemists will find this difficult terrain, but the successful application of magnetic resonance spectroscopy to the study of the catalytic mechanisms of several enzymes should be an incentive to the faint-hearted.

The final volume of *A Laboratory Manual of Analytical Methods of Protein Chemistry* is devoted to techniques for determination of molecular size and shape. As in the earlier volumes, each chapter is written by one or two experts. The volume opens with an account of methods of preparation of specimens for electron microscopy and the use of techniques such as shadowing, staining, and replication. The chapter on osmometry is a salutary reminder of what can be achieved with a combination of experimental skill and simple home-made equipment. One feels that the inclusion of a description of the electronic osmometer is an apologetic afterthought. In complete contrast, there follow reviews on the diffusion and ultracentrifugation of proteins with their heavy reliance on commercial instruments. The principles of the methods, however, rather than detailed descriptions of equipment, are emphasized. An account of the study of non-Newtonian liquids in capillary viscometers pays welcome attention to experimental difficulties and illustrates by numerical examples possible sources of errors.

Research on unimolecular protein films has too few exponents; perhaps the present discussion of techniques and their application to the determination of molecular weights and diffusion coefficients on the microscale will stimulate more interest in this field. The book ends with a description of the measurement of light-scattering by proteins; it emphasizes the particular suitability of this technique for determining the molecular weight and asymmetry of large proteins and also for studying the kinetics of processes such as aggregation and denaturation. Like its two forerunners, this volume contains a wealth of illustrations and tables. Bearing this and the number of contributors in mind, the price is very reasonable. It is a pity that differential ultra-violet spectrophotometry has not been mentioned, but perhaps its value has only been realized since this series was planned.

D. T. Elmore

CHROMOSOME NUMBERS AND TAXONOMY

Chromosome Numbers of Central and Northwest European Plant Species

By Áskell Lövé and Doris Löve. ("Opera Botanica" a Societate Botanica Lundensi, Vol. 5.) Pp. 581. (Stockholm: Almqvist and Wiksell, 1961.) 40 kronor.

THIS latest manual is intended as a reference work to the chromosome numbers so far reported for plant species and subspecies known to occur in central and north-west Europe as circumscribed by the authors. It lists 5,490 species and 1,360 subspecies of Pteridophytes, Gymnosperms and Angiosperms, of which chromosome counts are given for 4,417, that is, 80·7 per cent. Diploid and basic numbers are given: the basic numbers are calculated from the lowest diploid number known in the group in question, or are theoretical when only apparently polyploid numbers have so far been reported. An appendix lists new counts which have not been previously published, together with an indication of the source of the material and the name and institutional address of the worker concerned.

On the critical question of the taxonomic identification of the plants, the numbers of which are listed in the main text, the authors point out that most chromosome numbers are determined either by "cytologists lacking taxonomic training or by taxonomists lacking cytological skill and experience". They have not found it feasible to distinguish between those counts based on cultivated material and those based on spontaneous material.

This compilation must surely be the last of a distinguished series of chromosome lists to reproduce all numbers and counts reported, irrespective of the origin of the material or checks on its identity. What is now needed is much more selective chromosome information—for example, lists of accredited numbers for more restricted regions, discarding earlier or doubtful records and including only counts determined from spontaneous material growing within the region in question.

At the moment most chromosome number compilations, including the present one, serve more as a systematic guide to the relevant literature than as a basis for taxonomic, phytogeographical and similar conclusions. It cannot be stressed too often that reported numbers for species have to be sifted through and verified in perhaps the majority of cases before they can be accepted. If even the most elementary conditions are laid down before numbers are accepted for inclusion in, say, a Flora, it is surprising how few numbers in the literature are found to satisfy these conditions.

Certainly the Löves have performed a signal service in making the source references available to us (the bibliography runs to nearly 200 pages) and this book should find a place on all taxonomists' shelves. The introduction of some 15 pages, in addition to outlining the scope of the work and giving the limits of the area covered and statistical data, includes an essay on the systematic arrangement adopted and a section somewhat ambiguously entitled "Limitation of Categories". The point of view of the authors is summarized by their acceptance of Mayr's definition of species as "groups of actually or potentially interbreeding natural populations, which are reproductively isolated from other such groups". As readers familiar with the Löves' work will expect, they adhere to the view that, with certain exceptions, all taxa differing in chromosome number are logically regarded as distinct species. Consequently, they do not recognize infraspecific polyploidy (apart from sporadic variants), an attitude that receives diminishing support to-day.

These views affect, of course, the taxonomic treatment adopted in the text. This would be of little moment but for the fact that they have found it necessary to make a number of nomenclatural changes (the details published in *Botaniska Notiser*, 114: 33, 48; 1961), some concerning the status of the groups concerned, others consequent on the adoption of narrow generic limits, especially in cases where cytological evidence apparently lends support. Thus *Lycopodium* is split into *Lycopodium 'sensu stricto'*, *Diphasium*, *Lepidotis* and *Huperzia;* and *Euphorbia* into *Tithymalus*, *Agaloma*, *Poinsettia* and *Chamaesyce*.

The volume is well produced, as we have come to expect from *Opera Botanica*. There are several misprints and minor errors. The foregoing criticisms apart, the Löves are to be congratulated on their immense industry and patience in producing this work. It must have been indeed a labour of love.

V. H. Heywood

BIOLOGY AND HUMANITY

Biology and the Nature of Man

Based upon the Riddell Memorial Lectures Thirty-third Series delivered at King's College in the University of Durham on 7, 8 and 9 March, 1961. By Dr. W. H. Thorpe. Pp. xii + 122. (London, New York and Toronto: Oxford University Press, 1962.) 12*s*. 6*d*.

THIS collection of lectures by Dr. W. H. Thorpe, the thirty-third series of the Riddell Memorial Lectures, is in the manner and on the scale of the fourteenth series, namely, those delivered by the late Sir Edmund Whittaker. Biologist and mathematician respectively, they discuss the fundamentals of scientific theory and of belief: as a result they confirm the Christian religion in its sacramental aspect as paramount for the Universe and for experience. It is significant that the latter position at least is also reached on archæological grounds in a recent book by Prof. E. O. James. Taken all in all, this is a remarkable degree of agreement between a trio of scholars in such widely different fields of research.

In the chapters now before us, Dr. Thorpe discusses (1) the origin of man, (2) the mind of man and its origin, (3) the origin of man's moral nature, (4) the distinctiveness of man's moral nature, (5) the destiny of man. The terms of these lectures request that they should be given "with particular emphasis on and reference to the bearing of such developments on the ethics and tenets of Christianity". This wish has indeed been faithfully fulfilled. As a result, a distinguished natural scientist finds himself dealing with matters essentially theological and philosophical. As he truly says, it is because life and destiny are the concern of us all that this incursion must be undertaken. It might be added, not only that, but also trespass—if trespass it be—should be greeted as a major contribution to the whole edifice of truth. In classical times this would not have appeared strange: it is a comparatively modern misfortune that philosophy and theology have become 'departments' of knowledge rather than something to live by, and deriving much of their inspiration from every discipline which is "honest and of good report".

Dr. Thorpe's approach leads him to meditate on both metaphysics and mysticism. Concerning the former, there will always be axiological factors in biological systems (as even in quantum physics), associated with vestiges of teleology. In this context, one would expect perhaps some reference to the late Dr. E. S. Russell's 'directiveness': and so far as mysticism is concerned, this has often been the goal of the deepest philosophical contemplation, a curve of awareness tending to the inexpressible as an asymptote. Maybe it is difficult for some minds to admit this; to others it seems obvious and even welcome.

On page 88 is a reference to form, and the possibility of its analysis "into energy *plus* organization" (my italics). Is this quite right? I have investigated an analogous problem myself (1939, 1946) with energy as a *function* of organization. Then the integral is of the nature of a potential, which is suggestive.

We can but thank Dr. Thorpe for a set of essays (as they are now) of such absorbing interest. They contain an element of Spinoza's statement of 1677, which may be translated thus—"The effort by which each thing tries to persist in his own being is nothing but the essence of the thing itself". F. I. G. RAWLINS

HUMAN GROWTH

Growth at Adolescence

By Dr. J. M. Tanner. Second edition. Pp. xiii + 325 + 11 plates. (Oxford: Blackwell Scientific Publications, 1962.) 47*s*. 6*d*. net.

THIS is the second edition of a well-received book on human growth and development which appeared first in 1955. It now comes in an improved and extended form, and Dr. Tanner promises that in the next edition he will cover all aspects of the growth and development of children. Already the title of the book inadequately describes its contents.

There is no other text in Great Britain which gives the same comprehensive survey of human growth—its measurement, its velocity, the factors affecting it and the total aspects of physiological maturation. Dr. Tanner, with the help of his assistant, Mr. R. H. Whitehouse, has himself provided much of the data regarding the velocity of growth in Britain. The Harpenden Growth Society which he initiated, with the help of the Ministry of Health, is well advanced in the longitudinal study of children from birth to puberty and beyond.

He discusses the merits and disadvantages of cross-sectional and longitudinal studies of growth. Cross-sectional measurements can provide information on the distance curve of growth and the mean age of a certain stage of maturation, such as the menarche, but for velocity curves, and particularly for the facts concerning the variation of velocity, longitudinal studies are necessary. Doctors and others concerned with the development of individual children employ a useful convention in assessment which the author discusses fully—it refers to a child's skeletal age, dental age, height age, weight age, and so on. This method requires the provision of accurate standards for development in both sexes and at any age, and for all parameters of maturation these are increasingly available. Clinicians seek to use these conventions both for immediate assessment and for prediction. There are many difficulties in so doing—of which one simple example is provided by the short child. Is the child's linear growth retarded by some ascertainable environmental factor, by the inheritance of short stature, or are both influences at work? There is in the book an interesting example of the necessity and value of prediction. The School of the Royal Ballet admits its pupils at the age of nine years and, having strict limits for the mature height of its ballerinas, now excludes those girls whose chance of ending between the limits is under 5 per cent.

The effects of disease and nutrition, good and bad, on development is a complicated and fascinating subject to which the author gives much attention. For example, can the advancing secular trend in height and the earlier age of sexual development be entirely related to improved nutrition and the reduction of disease? Other additional possibilities are discussed—in environment the rising world temperature and in inheritance that some degree of dominance exists in the genes governing stature and that heterosis is proceeding more rapidly (outbreeding has, in fact, increased at a fairly steady rate ever since the introduction of the bicycle). He is interested, as indeed we all must be, in the implications for our social and educational organization of the physiological fact of the steadily advancing age of sexual maturity, a process which is still continuing.

The author promises us an extension in the content of his next edition. While this will be welcome, he should consider exclusion as well as further inclusion and re-arrangement. It is obviously impossible for him to continue to include psychological and behavioural maturation and he might well decide to limit his book to physical and intellectual growth and development, excluding also the chapter on the physiological changes of adolescence. Excellent and indispensable though this edition is, it bears the marks of a book in transition. It contains an enormous collection of observations which have not always been assessed and digested, and the book would be much improved by a judicial summary of the evidence at the end of each chapter. Consideration, too, should be given to the bibliography, which is valuable but excessive, occupying one-sixth of the book and totalling many more than a thousand references. I myself failed to understand the relevance of the quotation from Edward Lear on the fly leaf, but perhaps the author intended to launch his book on the "sea in a Sieve", hoping that it would return to him with the small amount of dross separated from the preponderant good.

DOUGLAS HUBBLE

HORMONE RESEARCH

Recent Progress in Hormone Research

Vol. 17: Proceedings of the 1960 Laurentian Hormone Conference. Edited by Gregory Pincus. Pp. viii + 600. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1961.) 100*s*.

THIS volume contains fifteen papers presented at the Laurentian Hormone Conference during September 4–9, 1960. The aim of the Committee which arranges these conferences is to present a contemporary view of developments in selected topics of experimental endocrinology. Four main themes were covered at the conference, namely, testicular function, hormones and reproduction, aldosterone and electrolyte metabolism, and finally hormones and organic metabolism.

The first section contains two papers, one on endocrinological factors which influence the histology and function of non-neoplastic interstitial cells in the mouse. The other paper in this section deals with fascinating observations on genetic aspects in male hypogonadism.

The subject of hormones and reproduction is dealt with in five papers, of which the first is a nutritional-endocrinological study on the effect of dietary erucic acid on testicular function in the rat. The other four papers in this section are concerned with the endocrinology of female domestic mammals, oestrogen metabolism in the human fœtus and new-born, the transplacental passage of steroid hormones and a paper on the metabolic effects of progesterone in man.

The largest single portion of the volume is devoted to six papers on hormones and electrolytes. The subjects covered include: mechanisms regulating the control of aldosterone, mechanisms of oedema formation, primary aldosteronism, the physiology of the posterior pituitary and its effects on permeability of membranes, etc.

The volume concludes with two papers on the regulation of glucose uptake by rat heart muscle and the effect of insulin and other hormones on the isolated perfused rat liver.

This volume maintains the high scientific standard set by the sixteen previous issues and contains a series of informative chapters by experts in diverse areas of hormone research. Like its predecessors this volume contains an "edited discussion" after each communication. Conferences require discussion, but the value to the reader of the inclusion of discussion in the published text might be reviewed by the organizers or the editorial axe could be used advantageously here and there.

The book is well produced and illustrated and this series is now an obligatory annual reference book for all endocrinologists; in addition, this volume will appeal to many other biologists. G. S. BOYD

PAPER SCIENCE

Formation and Structure of Paper

Transactions of the Symposium held at Oxford, September, 1961. Edited by Francis Bolam. Vol. 1: pp. x + 535 + xliv + 34 plates. Vol. 2: pp. viii + 536–910 + xliv. (London: Technical Section of the British Paper and Board Makers' Association (Inc.), 1962.) £10 10s.

FOR the first twenty-five years after its foundation in 1920 the Technical Section of the British Paper and Board Makers' Association depended, for its publications, on the research efforts of very few men. For a long time there was only one qualified worker in the whole British paper industry and many technical papers were written by busy routine workers in their spare time. Some indeed were officially discouraged from attending meetings of the Technical Section in case they 'gave anything away'. By the end of the First World War the climate of opinion was changing. The British Paper and Board Industry Research Association was established at Kenley and several of the larger companies set up research laboratories.

An international conference on paper technology was successfully convened in Paris in 1955 by the French organization 'L'ATIPE' and increasing numbers of British technologists were able to attend similar meetings in the United States. The fundamental research committee of the Technical Section arranged a successful symposium in Cambridge in 1957 and its proceedings were later published as *Fundamentals of Papermaking Fibres*, edited by F. Bolam, Technical Section, 1958. At the conclusion of that conference it was decided that another symposium on *Formation and Structure* should be held in Oxford in 1961 and the two volumes under review are the transactions of this meeting.

At each symposium the contributors came from the United States, Canada, Australia and several European countries as well as from Great Britain. The Cambridge symposium was to a considerable extent a review of existing knowledge and is very useful to teachers of paper science.

The Oxford symposium, with its subject announced four years ahead, attracted a much larger proportion of new work than the Cambridge meeting and is, probably, of more interest to research workers. In summing up the conference at its conclusion, Prof. Rånby (Stockholm) said, "What has been presented here has, indeed, advanced our knowledge of the structure and basic properties of paper. In particular, I congratulate our British colleagues, who have contributed so beautifully in this field of research, which we previously did not think of as a speciality for this country". The early members of the Technical Section who struggled with what was known, most incorrectly, as "Paper Chemistry" with desperately little equipment and negligible library facilities might feel indeed that "the wheel is come full circle".

Paper is a porous assemblage of fibres, and it is difficult to describe its properties in precise scientific terms. Even its thickness is indeterminate; the value measured depends so much on the pressure used in the micrometer that it is best to avoid quantities like stress which necessitate the use of thickness in calculation. There are numerous empirical physical and chemical tests well used in commercial specifications.

The papers given at the Oxford symposium are a noteworthy attempt to view paper in more fundamental terms than usual. Corte and Kallmes have shown that many properties can be explained by the statistical geometry of random straight lines. For studying the permeation of fluids a paper may be considered to be built up from very thin networks which are themselves composed of random polygons built from these straight lines. There are many excellent photomicrographs of the surface structure of paper from Kenley, electron micrographs of different parts of fibres from Darmstadt and photographs of paper made with the scanning electron microscope in Montreal. Page and Tydeman (Kenley) develop a theory to explain the anisotropic tensile and hygro-expansive properties of paper in terms of structure and show in particular that the compressive forces which occur in drying can cause fibres to contract longitudinally and frequently to exhibit micropuckering. This is confirmed by electron micrographs from Montreal introduced into the proceedings after the conference.

The early Chinese paper-makers discovered that paper could be made from vegetable fibres by suspending them in water and drying them without any other adhesive, but the reasons for the adhesion are still debated. The current hydrogen bonding theory and visco-elastic properties related to it are developed by Nissan. Bonds between fibres can be seen to break (Page) and heard to break (Corte) while the stresses within fibre joints can be treated and clarified mathematically (Van den Akker). There still seems to be some discrepancy between the views of paper scientists and colloid chemists as regards the distance over which bonding forces can act.

A simple but ingenious method for breaking up paper and analysing the clay-fibre ratios at different levels through its thickness is described by Groen. Investigations on uniformity, flocculation and wet end variables are described by Robertson and Mason and by Wrist. Only a few of the many interesting papers can be mentioned here; in the two volumes there is plenty of mathematics and physics, some morphology and scarcely any chemistry. Rånby's summary and Rance's introduction are two of the most valuable chapters and should be read first.

The issue of the main papers as preprints before the conference gave rise to lengthy discussions which are reported in full. A number of contributors succeeded in introducing sizeable papers at this stage. This, and the lack of brevity of some authors, mentioned in Rånby's summary may account, in part, for the high cost of the book. Some of this must, however, be due to the numerous micrographs which are exceptionally well reproduced.

It is difficult to see how more information on structure could have been collected in the present state of knowledge even though some might, perhaps, have been left out. It is expected that the book will sell well all over the world to those interested in advancing the subject of paper science.

F. LYTH HUDSON

Neutron Physics

Proceedings of the Symposium held at Rensselaer Polytechnic Institute, May 5–6, 1961. Edited by M. L. Yeater. (Nuclear Science and Technology, a Series of Monographs and Textbooks. Vol. 2.) Pp. xiii + 303. (New York and London: Academic Press, Inc., 1962.) 86s.

THIS volume reports the Proceedings of the Symposium held at the Rensselaer Polytechnic Institute in May, 1961, to mark the opening of the Neutron Physics Laboratory and its high-intensity linear electron accelerator. The papers presented cover all areas of neutron physics work, including nuclear physics measurements on fissile and non-fissile nuclei, solid and liquid state research and neutron thermalization problems. In addition, there is one paper on the fusion problem. Unfortunately, with such a wide range to cover, some limitations are inevitable. In effect this book presents a review of the resonance region neutron cross-section field and the thermalization field, while the other subjects are only covered in part. But, as a review of the cross-section field, it is marred by the very fact that it is a compilation of papers which present the results obtained in individual laboratories with individual machines, rather than broad surveys. Thus, while this book is quite useful in giving a picture of these fields to a 'new-comer', it is unable to compete with the text-books on neutron physics which are being published by the same publisher.

The style is informal in that the papers were prepared from tape recordings taken at the meeting, and the articles read as though they were being spoken rather than prepared in the manner of a text-book. This fact, coupled with the good layout of the book, makes it very easy to read. On the whole this is an interesting and useful book but one likely to have a rather short life.

P. A. Egelstaff

Brompton Hospital Reports

Vol. 30, 1961. (A Collection of Papers by Members of the Staffs of the Hospitals for Diseases of the Chest (Brompton Hospital; London Chest Hospital); and of the Institute of Diseases of the Chest.) Pp. viii + 287. (London: Lloyd-Luke (Medical Books), Ltd., 1962.) 15s. net.

FOR many years papers published by the staffs of the Brompton Hospital, London Chest Hospital and the Institute of Diseases of the Chest have been brought together in a composite volume which is issued annually. The thirtieth of these is notable for an article by Sir Russell Brock on the surgical treatment of pulmonary stenosis and a series of articles dealing with various aspects of sarcoidonis. There is also a description of a quantitative method of studying tumour cells in blood by Drs. S. W. A. Kuper, J. R. Bignall and E. D. Luckcock as well as an assessment of antitussive drugs in man by Dr. F. J. Prime. Dr. Lynne Reid examines the relationship between chronic bronchitis and the hypersecretion of mucus, while Dr. J. H. Ross reviews the surgery of the thoracic duct. In the main the articles are written in 'popular' style and are well supported by diagrams and photographs.

T. H. Hawkins

The Exploration of Outer Space

By Sir Bernard Lovell. Pp. ix + 87. (London: Oxford University Press, 1962.) 16s.

THIS is an introduction for the layman to some of the recent developments in astronomy, particularly those involving radio methods of investigation. Sir Bernard's skill in popular exposition is well known, and this book bears out his reputation.

It is based on the Gregynog Lectures, given in Aberystwyth in October 1961, and starts with a chapter on techniques followed by further chapters on the solar system, the structure of galaxies and the origin and evolution of the universe. With all this in 87 octavo pages there is obviously no room for details but most of the problems at present engaging attention in the field find at least a mention.

The final chapter is on extra-terrestrial life and the possibility of detecting it. The author gives a strong warning about the danger that the U.S.S.R. or the United States might inadvertently contaminate other planets with organisms from the Earth and perhaps destroy our chance of studying their own life-forms, if any. This warning comes over with particular force when it is remembered that Sir Bernard's criticisms of high-altitude nuclear explosions were 'pooh-poohed' by 'responsible' scientists before the event of July 9, 1962, but are now seen to have been largely justified. The last chapter also describes the recent attempts to receive 21-cm radio waves from intelligent beings on nearby stars. It is ironical that these attempts have already been overtaken by scientific progress, for coherent light from lasers is now considered to be a more effective method of communication over interstellar distances and who can say what will be the best technique available in even ten, let alone a hundred or a thousand, years' time?

J. R. Shakeshaft

The Annual of the British School at Athens, No. 56, 1961

Pp. x + 228 + 31 plates. (London: The British School at Athens, 1962.) 105s. net.

THE 1961 *Annual* maintains the British School's high standard of archæological publication. The weight of this volume is given to two subjects, topography and epigraphy; but numismatics, excavation publication and early Athenian history are also treated and there is an article about ancient Greek kilns and their "double stoking tunnel".

D. M. Metcalf discusses the Byzantine scyphate (saucer-shaped) bronze coins in Greece during the twelfth and early thirteenth centuries. From a study of hoards and site-finds he assigns certain types to areas and suggests possible mints. M. F. S. Hood and J. Boardman publish three early Iron Age tombs at Knossos, Crete; mainland Greece is represented by the publication of evidence for Mycenæan occupation near the Cyclopean Terrace Building at Mycenæ and by two pieces of a chariot larnax from the same site. Prof. Hopper's article on the early history of Athens destroys the thesis that there was a connexion between the three 'regions' of ancient Athens (Plain, Shore, Hill) and political parties later imagined to have been based on them. The author attempts to reconstruct Athenian history in the seventh and sixth centuries B.C. and sees political parties as fluctuating groups supporting particular individuals who were mostly concerned with advancing their own political interests. Thus he expresses a view of ancient Athenian politics coming increasingly to the fore, displacing the accepted idea (based on modern and political theory) of 'conservatives', 'moderates' 'radicals'.

The emphasis on topographical research is a marked feature of Greek archæology to-day. The famous sites are for the most part dug and published and so the topographers have taken the field and are doing valuable work in establishing the relations of small outlying sites to main centres, in working out the chronological patterns of settlement in specific areas and in identifying sites for which literary evidence exists. In this volume Helen Waterhouse and R. Hope Simpson present (at perhaps excessive length) the second part of their exploration of prehistoric Laconia, J. M. Cook argues for identifying four small classical cities near ancient Miletus in Turkey, and Garnett and Boardman publish the results of underwater reconnaissance off the island of Chios in 1954.

For epigraphy, A. Schachter publishes ten small inscriptions from Boeotia and Ursula Duncan writes on lettering by Attic masons. T. B. Mitford gives the formal publication of the 113 Hellenistic inscriptions from Old Paphos in Cyprus. Twenty-one of these are new, and two are important.

Peter Warren

SHAPE DISCRIMINATION AND RECEPTIVE FIELDS

By DR. N. S. SUTHERLAND
Institute of Experimental Psychology, University of Oxford

THE problem of how patterned stimuli are analysed by the nervous system is important but until recent years has been neglected. It is important since unless we know how incoming stimuli are coded, we cannot say anything very helpful about the further processing mechanisms in the nervous system which lead to the overt response. It has been neglected since until recently the tools were not available to attack the problem. Three developments in three different disciplines have brought promise of a solution. Psychologists can apply the 'method of stimulus equivalence' pioneered in the 'thirties by Klüver and by Lashley, and thus can attempt to discover the categories into which incoming information is sorted. Physiologists are able to throw direct light on the coding of incoming information by the newly developed technique of microelectrode recording. Recent developments in electrical engineering suggest that complex recognition tasks can be performed by systems simple enough to be understood and even built. In addition to the contribution made by developments in the foregoing three subjects, important evidence is, of course, also provided by neuro-anatomists using longer established techniques. Developments in other disciplines have made it easier to give functional interpretations of patterns of connectivity in the nervous system, and the direct study of such patterns by anatomical means in turn assumes a new importance.

The work with which this article deals is relevant to one aspect of the general problem, namely, how animals recognize visually presented shapes.

In 1957, I put forward a theory about shape recognition in the octopus[1]. Predictions made from this model were afterwards tested by behavioural experiments and the status of the model was reviewed in *Nature* in 1960[2]: although the theory was not without its critics, it was able to handle most of the evidence then available. More recently collected results suggest that some details of the theory require modification. Deutsch[3] and Dodwell[4] have also proposed theories to account for shape discrimination in the octopus; despite their ingenuity, both theories leave some evidence unaccounted for[5].

The aims of the present article are: (1) to summarize some new results on shape recognition in the octopus and other species; (2) to show where my theory fails to explain these results; (3) to suggest a modification of the theory which both fits with recent physiological and neuro-anatomical findings and helps to explain the recent behavioural data. Before discussing these topics, a brief description of the problem and the methods used will be given, and the original theory stated.

Problem and Method

The problem is to discover what are the physical properties or dimensions in terms of which animals classify shapes and to infer the type of analysing mechanisms at work in the brain. Although it is clearly impossible to specify brain mechanisms with certainty on the basis of behavioural evidence, the attempt is worth making because such models have heuristic value in the collection of fresh behavioural and physiological data. Moreover, if the dimensions of analysis are complex it may be very difficult to specify them without having some model in mind.

Two behavioural methods have been used: (1) animals are trained to give different responses to the members of various pairs of shapes in order to establish which pairs are readily discriminated, which are difficult or impossible to discriminate. (2) After training, animals are given 'transfer tests' with other shapes in order to establish to what extent these new shapes are treated as similar to one or other of the originals. The two methods are complementary.

A simple example will demonstrate the sort of inference it is possible to make by the use of these methods. If the primary property of shapes analysed were the number of sides, then a square and a triangle should be easier to discriminate than a square and a diamond (method 1). Furthermore, after training on a square and a triangle, animals should give the same response to a diamond as that which they have learned to make to a square (method 2)—in practice, octopuses treat a diamond like a triangle not like a square, and this suggests that the number of sides (or angles) present in a shape is not one of the primary properties under analysis.

An attempt has been made to collect data from species widely separated phylogenetically (octopus, rat and goldfish) in the hope of uncovering differences in the way different species classify shapes. If consistent differences emerged this would provide a further clue to the dimensions under analysis and the mechanisms at work, particularly if such differences could be correlated with differences in neuroanatomy or environment[6].

The First Model

In 1957 a model was proposed which accounted well for many early findings[1,2]. It was suggested that in the octopus's visual system shapes were converted into their 'horizontal' and 'vertical projections'. The horizontal projection is arrived at by counting the horizontal extent of a shape at each point on the vertical axis, and the vertical projection by counting the vertical extent at each point on the horizontal axis (for some examples of such projections cf. Fig. 2). To explain the early evidence it was necessary to make the further assumption that behaviour is more readily determined by differences in the horizontal projections of shapes than by differences in their vertical projections.

Among the earlier findings which the model predicted or explained are the following. Octopuses discriminate very readily between a vertical and horizontal rectangle, but scarcely at all between two rectangles, one set at 45° to horizontal, the other at 135°. The discrimination of a horizontal or vertical rectangle from an oblique rectangle is of intermediate difficulty. M and Λ shapes having identical projections are very difficult to discriminate; after learning to discriminate M from >, animals treat Ʒ as equivalent to the original >, and Λ as equivalent to the original M. Shapes reversed along the horizontal axis are less readily discriminable from one another than shapes reversed along the vertical axis. Two horizontal rectangles differing in length are more readily discriminated than two vertical rectangles differing in length. After being trained to discriminate a square and a vertical rectangle there is a tendency to treat a horizontal rectangle as equivalent to the square. A square and a triangle are more readily discriminable than a diamond and a triangle. After training on square and circle there is no tendency to treat a diamond as equivalent to the square. For a fuller description of these results and for references to the experimental papers see ref. 2. All these findings were originally obtained with octopuses, but some of them have since been replicated with other species, namely, rats[7], goldfish[8], monkeys[9], and children[10].

Some Recent Data

It is impossible to summarize fully all the more recently collected behavioural data on shape discrimination. Attention will be focused on data which it is difficult or impossible for the original model to explain.

(1) *Republicated patterns.* The two patterns shown in Fig. 1 should, according to the theory, be impossible to discriminate. Whether the white portions of the patterns or the black are counted, the projections of each pattern are the same and are as shown in Fig. 1. Despite this, the two patterns are very readily discriminated by octopuses[11]. Indeed, they are much easier to discriminate than are a single horizontal and a single vertical rectangle of the same size as each of the elements in the two patterns.

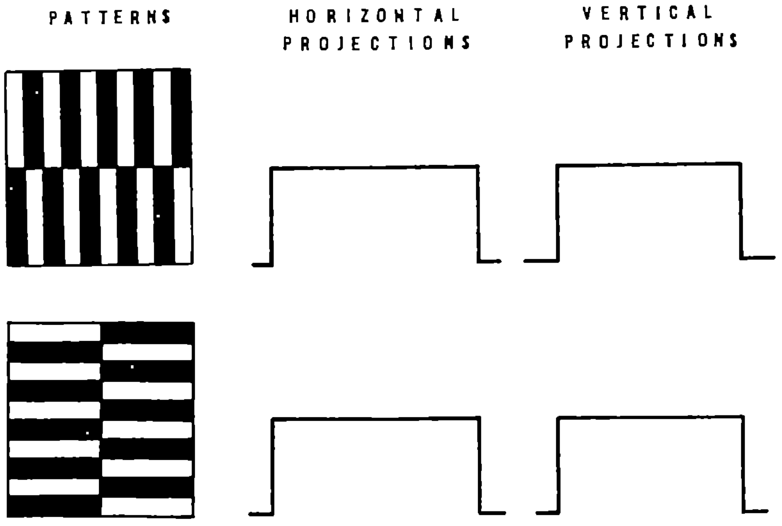

Fig. 1

(2) *Horizontal and vertical projections.* Since the theory assumes that differences in horizontal projections are more readily detected than differences in vertical projections a pair of shapes differing solely in the former projections should be more readily discriminable than a pair differing solely in the latter. From Fig. 2, it will be seen that pair 1, 2 differ only in their vertical projections whereas the members of pair 3, 4 differ only in their horizontal projections. Nevertheless, the first pair was found to be as readily discriminable by octopuses as the second[12]. Pairs 11, 12 and 13, 14 were also found to be equally discriminable although again one pair differs only in vertical projections, the other only in horizontal[13]. The same finding was obtained with pair 5, 6 and the pair made up of the 90° rotations of these shapes[14].

(3) *Open and closed shapes.* If animals are trained to give response x to shape X and response y to shape Y and are then shown several transfer shapes, we can count up how often each response is given to each transfer shape and thus rank order the transfer shapes starting with that to which most x responses are given and ending with that to which most y responses are given. Perhaps the most interesting recent finding is that when the same transfer shapes are presented in different experiments, they are frequently arranged in the same order despite wide variations in the pairs of training shapes used[7,12-14]. Thus after training on any of the seven pairs of training shapes shown on the left-hand side of Fig. 2, octopuses arrange the transfer shapes shown on the right-hand side of the figure in the same order. This suggests that the members of pairs of training shapes producing this ordering of transfer shapes themselves differ along one of the primary dimensions used by the octopus in the analysis of shape. The problem is to specify this dimension by examining the way in which transfer shapes are ordered along it. Early work[7,14] made it appear possible that a shape's position on the dimension might be determined simply by the ratio of its periphery to the square root of its area. Later work[13,15] suggested that this was incorrect since changing the orientation in which a shape was presented altered its position on the scale. Although we cannot define

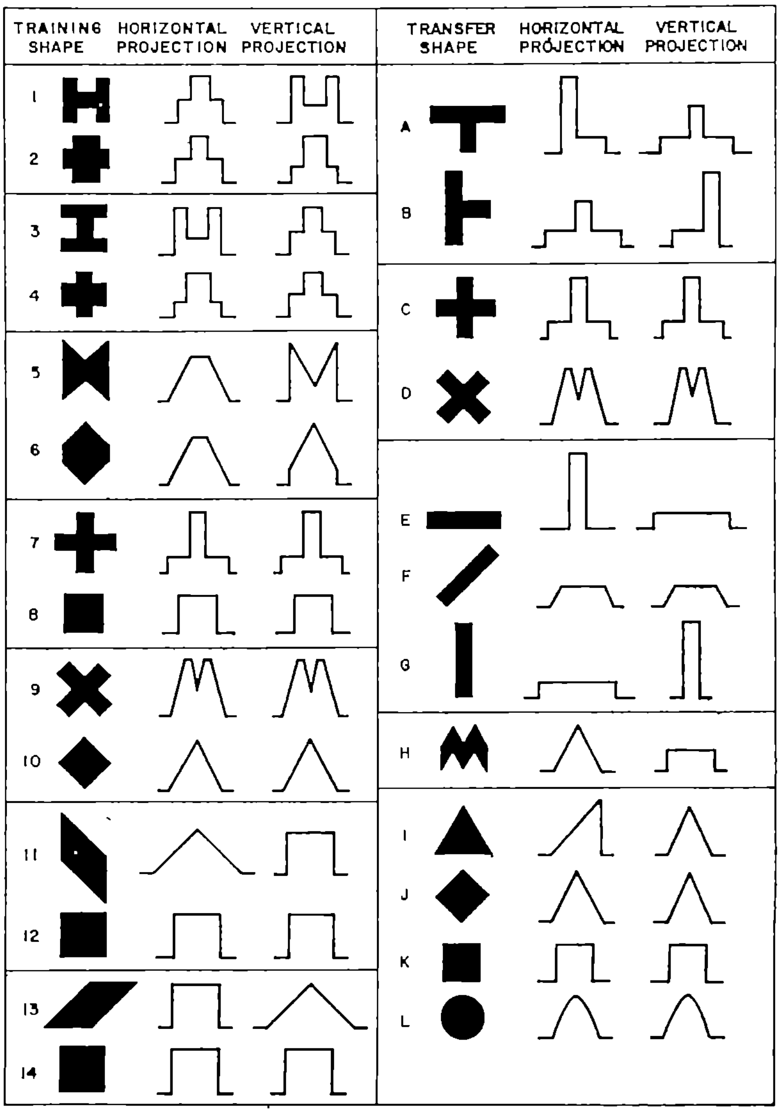

Fig. 2

the dimension in question precisely until we have discovered exactly which physical properties of shapes determine their position on it, it is useful in the meantime to name it. Since shapes at one end of the dimension appear to human beings spread out or open, whereas at the other end they appear compact or closed we shall refer to the dimension as 'open–closed'. Of the training shapes shown in Fig. 2, the odd-numbered member in each pair lies towards one end of the dimension (open), and the even-numbered shapes lie towards the other end (closed). In what follows the words 'open' and 'closed' will be used to indicate the position of shapes on a scale: it is important to remember that their position was determined experimentally—the octopus not the experimenter decides whether one shape is more or less open than another.

Octopuses were trained on each of the training pairs shown in the first column of Fig. 2 (and on several others not shown) and were then presented with various transfer shapes some of which are shown in the fourth column. The more open a transfer shape was found to be (that is, the more nearly it was treated in the way the animal had learned to respond to the open training shape), the higher its position in Fig. 2. Shapes lying inside the same pair of horizontal lines definitely lie along the dimension in the order given—thus *C* is more open than *D*, *E* is more open than *G*, etc. The position of blocks of shapes along the dimension is, however, only approximate. Thus *D* is probably but not certainly more open than *E*. To determine exactly the relative positions of such shapes further experiments are necessary.

One interesting feature of the ordering of the transfer shapes is that the position of a shape on this dimension often depends on its orientation: thus the square and diamond (*J*, *K*) are the same shape shown in different orientations, but the diamond is always found to be more open than the square. Similarly, an upright cross (*C*) is more open than an '*X*' (*D*), and a horizontal rectangle (*E*) than a vertical (*G*). One general finding is not shown in Fig. 2. It will be noticed that the original training shapes were all filled-in block shapes. If, after training, an outline version of any of the original open shapes (odd numbers) is presented, it is always treated in exactly the same way as the animal had learned to treat the original open shape. If an outline version of any of the original closed shapes (even numbers) is presented, there is either no transfer at all, or the animal tends to respond to it in the same way as it had been trained to treat the original open shape.

There is, then, a remarkable consistency in the way octopuses order transfer shapes when different training shapes are used. Even more remarkable is the fact that two other species have been found to order transfer shapes in the same way as the octopus. Rats and goldfish were trained on pair 5, 6 and the 90° rotations of these shapes. Most of the transfer shapes shown here were afterwards presented and within the limits of experimental error they were ordered from most open to most closed in the same way in which they were ordered by octopuses. It therefore seems likely that the results obtained with octopuses have considerable generality, and many of them hold for species widely different phylogenetically.

We must now consider how well the original model explains the ordering of shapes along the 'open–closed' dimension. It will be noticed that the more open member of each pair of training shapes yields at least one projection which contains more or sharper peaks than occur in the corresponding projection of the closed members (Fig. 2). In general, the ordering of transfer shapes agrees well with the number and sharpness of the peaks occurring in their projections; thus, the diamond (*J*) yields more of a peak on both projections than does the square (*K*). Moreover, shapes yielding a high peak on their horizontal projections (*A*, *E*) are more open than shapes yielding the same peak on their vertical projections (*B*, *G*) and this agrees with the assumption that horizontal projections determine behaviour more readily than vertical. However, in three instances this analysis fails to predict the correct order. The circle (*L*) yields more of a peak on both projections than does the square (*K*) but it is a less open shape. The oblique rectangle (*F*) yields no peaks but is a comparatively open shape. It is not clear that the upright cross (*C*) yields more peaked projections than the '*X*' (*D*).

A Revised Model

At the time the original theory was proposed there was little physiological evidence available as to how the visual input was coded. Evidence of quite complex kinds of coding has recently been forthcoming from microelectrode studies on the visual cortex of the cat[16] and the tectum of the frog[17]. Hubel and Wiesel have discovered in the striate cortex of cat neurones which have elliptical receptive fields. One type of receptive field has an excitatory centre strip running longitudinally flanked by two longitudinal inhibitory strips. A neurone having such a field will only give a maximal response when a rectangle is laid along the length of the field covering only the excitatory centre strip. A small rotation of the rectangle abolishes the response, since when the rectangle is not in the same orientation as the elliptical field it covers both excitatory and inhibitory areas. In the cat striate cortex such neurones occur with receptive fields orientated in all visual axes. Hubel and Wiesel have discovered several other types of receptive fields, some of them considerably more complex in their properties than that described: these complex fields probably represent a further stage of analysis. It is unnecessary to describe in detail the other receptive fields discovered in the cat: they all seem to have the property of responding maximally either to a narrow bar or to a straight edge, though some are more affected by movement of the stimulus, etc., than others.

We cannot, of course, infer from the existence of a given type of receptive field in the cat to its existence in a species as phylogenetically different as the octopus. However, at the same time that Hubel and Wiesel were investigating coding in the cat's visual pathways by microelectrode methods, J. Z. Young was studying the neuroanatomy of the octopus's optic lobe. He obtained evidence that the dendritic pick-up fields in the optic lobe of *Octopus* are predominantly elliptical, and that there is a maximum number orientated in a plane which corresponds to the visual horizontal, a second maximum in the plane corresponding to the visual vertical, and fewer in intermediate orientations[18]. It is possible that Young has discovered in the octopus the anatomical basis for a coding arrangement similar to that demonstrated to exist by physiological techniques in the cat. It should also be noted that this type of coding is not dissimilar to that previously suggested by me[1] on the basis of behavioural evidence alone, though there are important differences.

If we assume that in the octopus brain the counting of visual extents is performed by a mechanism similar to that uncovered by Hubel and Wiesel and that (following Young) there are more neurones with horizontal receptive fields than with vertical and more with vertical than with oblique, then most of the behavioural data on shape recognition in the octopus can be readily explained. It is necessary to assume only that an open shape is one which fires many receptive fields and a closed shape one which fires few. Any thin segment of a shape will tend to fire receptive fields of the type described here, and thin segments occur not only where a portion of a shape is rectangular or elliptical but also at any corner.

Fig. 3 shows some shapes superimposed on receptive fields that have a centre excitatory strip flanked by inhibitory areas. It must be remembered that the extent

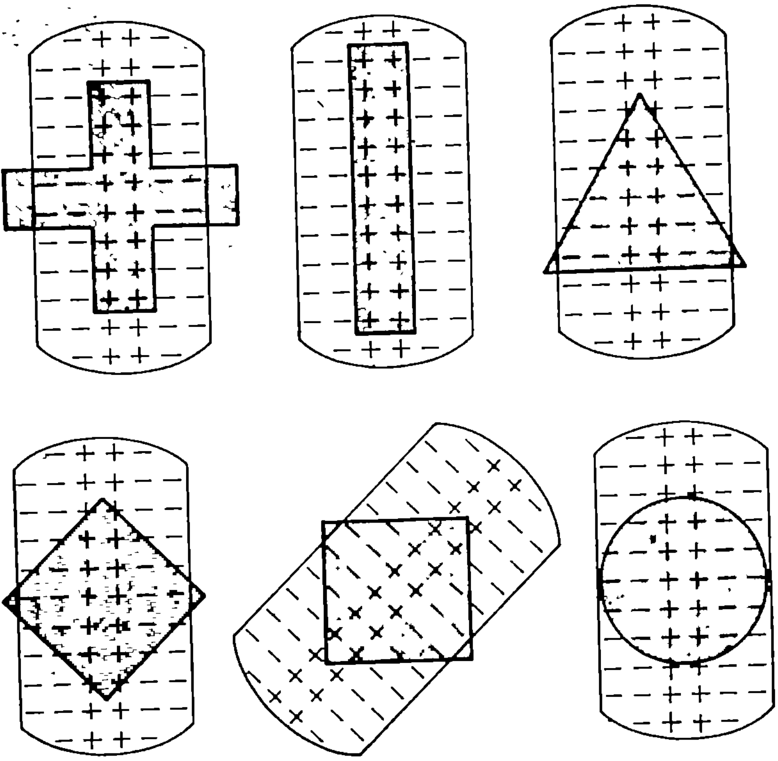

Fig. 3

to which a given neurone is fired depends on the excess of excitatory area over inhibitory area stimulated in its receptive field, that is, firing rate will vary with E–I, where E is the number of excitatory units stimulated, I the number of inhibitory. If we count each 'plus' in Fig. 3 as one excitatory unit, and each 'minus' as one inhibitory unit, then the value of E–I for each shape is cross 10, rectangle 20, triangle 0, diamond 0, square 0, circle -5. However, only the cross and the rectangle have been drawn in such a position as to maximize the value of E–I. If the triangle is superimposed on the field so that the base falls below it and the apex protrudes into it then the triangle yields an E–I value of 4. Similarly, if the diamond and the square are drawn with only one corner sticking up into the receptive field they each give an E–I value of 2. No matter in what position the circle is placed on a field E–I must be zero or less. It is clear that the extent to which a receptive field is stimulated by a given shape depends on the exact position in which that shape is placed on it. Variations in the receptive fields themselves will also result in variations in their tendency to be fired by different shapes. Thus, if we imagine a receptive field consisting of a central column two excitatory units wide flanked by one inhibitory unit on each side (instead of two as shown in Fig. 3), then all the shapes will have an E–I value greater than zero even placed in the positions in which they are shown in Fig. 3. This type of arrangement of excitatory and inhibitory units seems less useful than that shown in Fig. 3, since fields having equal numbers of excitatory and inhibitory units could be strongly fired by almost any shape merely by placing the shape slightly off centre on the field so that two excitatory units were stimulated for each inhibitory unit. Although the change in the arrangement of the field just envisaged results in a change in the absolute value of E–I it does not in fact alter the rank order of the values for the different shapes when placed in such a position as to maximize E–I. As we have seen, this rank order from most to least firing is rectangle, cross, triangle, diamond = square, circle.

It is clear that even if the actual distribution of excitatory and inhibitory units in a field is specified, it is not easy to calculate the total amount of firing each shape would produce since, whatever a shape's position on the retina, it will fall simultaneously on many overlapping receptive fields. Intuitively, however, it seems likely that the total amount of firing produced by different shapes will correlate with the maximum possible value of E–I for each shape.

In order to estimate the relative amount of firing produced by different shapes, we must also consider how far each shape will fire fields in different orientations. Thus, of the shapes drawn in Fig. 3, it is clear that the cross, triangle and diamond would all fire horizontally orientated fields as well as vertical; the square would fire an oblique field orientated at 90° to that on which it is shown superimposed, whereas the vertical rectangle can only fire fields which are themselves vertically orientated. Since we have assumed that there are more horizontally orientated fields than vertically orientated a shape which fired predominantly horizontal fields would actually produce more total firing than one which fired predominantly vertical fields. Similarly, it must be borne in mind that in the octopus there are probably more fields in a vertical orientation than in an oblique orientation. We can now try to estimate relatively how much firing will be produced by different shapes in order to see whether their positions on the 'open–closed' dimension (Fig. 2) can be accounted for in terms of the amount of firing they produce.

It is clear that a circle should be the most closed shape: it has no corners, and no matter how it is placed on a receptive field little or no firing can result. A square will be less closed since some firing of obliquely orientated receptive fields may occur where a corner of the square projects into such a field. A diamond should be less closed than a square since it will fire predominantly horizontal and vertical fields rather than the obliquely orientated fields fired by a square, and we have postulated that there are fewest fields in oblique orientations. For the same reason an upright cross will be more open than an 'X'. Again, a horizontal rectangle will be more open than a vertical since the former shape will fire horizontal fields the latter vertical and it is assumed that there are more horizontal fields than vertical. However, if there are more vertical than oblique fields an oblique rectangle should be less open than a vertical, but the octopus treats it as a more open shape. This discrepancy does not appear in the results from the goldfish. Despite its jagged appearance to us the M shape will not be particularly open since its various arms will tend to excite inhibitory as well as excitatory areas of receptive fields. Outline shapes will be more open than the corresponding filled-in shapes since they contain long, thin segments.

Most of the remaining data on open and closed shapes summarized under 3 above can be accounted for in similar ways. However, it is necessary to assume that as well as a count of the total number of neurones excited (giving the position of a shape on the open–closed dimension), an analysis is also performed of the proportions of neurones fired with fields in different orientations. This second type of analysis would account for much of the earlier data. Moreover, even when training shapes do differ on the 'open–closed' dimension, there is evidence that transfer is determined to some extent by whether the orientation of thin segments in transfer shapes is the same as or different from that of the segments of the open training shape.

The revised model based on Hubel and Wiesel's and Young's data will also allow us to explain the ease with which octopuses discriminate between the reduplicated patterns shown in Fig. 1 (point (1) here). Many more vertical fields will be fired by the first pattern than by a single small vertical rectangle and many more horizontal fields by the second than by a single small horizontal rectangle. Presumably the greater the number of neurones with fields in a given orientation that are fired by a shape, the easier it will be for further detection mechanisms to pick out the firing from a background of noise and therefore the more readily will the discrimination be learned.

The findings reported under point (2) here are not so readily explainable under the revised model. Thus the main difference in firing patterns between shapes 1 and 2 in Fig. 2 will be in the number of neurones fired having vertically orientated receptive fields, whereas the main difference for shapes 3 and 4 will be that 3 will fire more neurones with horizontally orientated fields than 4. It may be that when the difference in the number of horizontal fields or of vertical fields fired is great enough then no effect due to there being more horizontal than vertical fields will be detectable.

There is one further fact which the revised model explains better than the original theory. Sutherland and Muntz[19] investigated the preference of octopuses for different shapes in the absence of any training and discovered that the animals attacked shapes moving along their long axis much more readily than shapes moving across it. Rectangles moving along their long axis should excite the type of receptive field discussed here very strongly, whereas rectangles moved at right angles to their long axis should excite much less strongly since they will move over both excitatory and inhibitory areas of any given field. The octopus's preference for such shapes may be connected with the fact that crabs are its main prey, and crabs move along their long axis. It is likely that one of the features of crabs used in identification by cephalopods is the presence of legs[20]: again the type of mechanism discussed here would be well adapted to detect legs provided sufficiently small retinal fields were present.

The model here proposed raises many further questions. Three of these will be briefly delineated. (i) It is clear that with the type of retinal field arrangement discussed transfer of learning from one part of the retina to another could be achieved by linking up similar units from different parts of the retina to a common unit at a later stage, and Hubel and Wiesel provide evidence that this may occur. (ii) It is not so easy to envisage a mechanism which will result in the same output being given for a shape irrespective of its retinal size (size transfer). It may be that there are receptive fields of different sizes and the size actually used can be altered with the size of the shape under analysis. (iii) Only one type of receptive field found by Hubel and Wiesel in the cat has been considered in the foregoing analysis. This is because the findings on octopus suggest that in this species the length and orientation of thin segments of shapes are of primary importance in shape recognition, and this is precisely the sort of analysis made by the receptive fields discussed here. A second type of field discovered by Hubel and Wiesel seems to detect the orientation of contours rather than of thin segments of shapes. Recently acquired behavioural evidence from goldfish indicates that in this species contour orientation is more important for shape recognition than it is in the octopus. This suggests the exciting possibility that when both neurophysiological and behavioural evidence are available for a variety of species, we may be able to correlate variations in behaviour with variations in the proportions of different types of receptive field present in the brain of different species.

It has only been possible to give the barest outline of a revised model here, and clearly a great deal of further work remains to be done to test and develop it. For example, in order to account in detail for the ordering of transfer shapes it would be necessary to optimize various parameters of the model such as the actual widths and lengths of the receptive fields (in terms of visual angles), and the ratio of fields in one orientation to fields in other orientations. This could be achieved by means of a computer programme and the existing behavioural data are sufficiently extensive to evaluate the goodness of fit which resulted after optimization.

It is almost certain that the type of coding discussed here is only one of several types of coding proceeding in parallel in the visual system. Two simple operations have been suggested which could be performed on information coded in this way: namely, to count the total number of fields fired and to count the ratio of fields fired in one orientation to those fired in others. Obviously many other operations could be and indeed must be performed. Thus the two operations discussed would not detect a difference between mirror image shapes; since such shapes can be discriminated by the octopus (though only with great difficulty), some additional operations are required. It is suggested only that the two operations may be among the commonest performed in the visual system of *Octopus*.

GEOMAGNETIC AND PALÆOMAGNETIC EVIDENCE OF FOSSIL AXES OF ROTATION OF THE EARTH

By Dr K. M. CREER

Physics Department, King's College, Newcastle upon Tyne

PALÆOMAGNETIC work on Quaternary lava flows from many parts of the world indicates that the direction of the geomagnetic field averages that of an axial dipole over times of the order of 100,000 years. Individual readings of the field as given, for example, by precise measurements of the fossil magnetization of particular lava flows differ from the axial dipole field direction as does the direction of the geomagnetic field at the present epoch. The standard deviation of the distribution of individual flow measurements from a suite

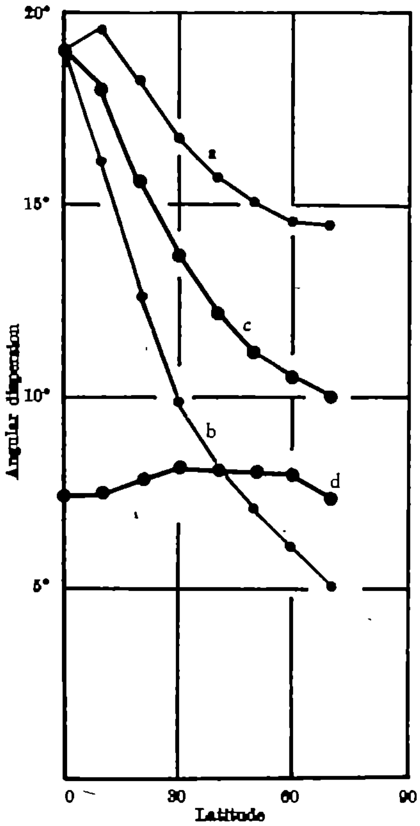

Fig. 1. Angular dispersion of 1945 geomagnetic field around lines of latitude: *a*, of field directions in southern hemisphere; *b*, of field directions in northern hemisphere; *c*, average of *a* and *b*; *d*, of virtual poles for northern and southern latitudes combined

of lava flows gives information about the palæosecular variation, but only a few attempts have been made by workers in palæomagnetism to compute this[1]. If each of N palæomagnetic readings of the field are represented by a unit vector and their resultant is R, an estimate of their standard deviation is given by an angular dispersion $\delta°$ equal to $\cos^{-1} R/N$. It may alternatively be supposed that each palæomagnetic reading is due to a non-axial but geocentric dipole and that the palæosecular variation is due to fluctuations of such dipoles about an axial mean[2]. The poles of such dipoles are conveniently referred to as virtual poles[3]. The palæosecular variation may also be estimated by calculating the angular dispersion of these.

The scatter of geomagnetic field directions at a given place during several tens of thousands of years may be estimated by rotating the present field about the geographic axis, and it has been shown by this means that the angular dispersion around lines of latitude is latitude-dependent and greater in the southern hemisphere than the northern[1] (Fig. 1). In a similar analysis of virtual poles[4] corresponding to geomagnetic field directions around lines of latitude higher dispersion factors are also observed for the southern hemisphere than for the northern, but when data for north and south latitude lines are combined the angular dispersions are independent of latitude (Fig. 1).

It was thought at first[1] that the higher dispersions in the southern hemisphere were due to chance. Of the ten or so regional sources of non-dipole field, more now happen to lie under the southern hemisphere than the northern but the situation might be reversed in time, the time-constant of such a source being about 2,000 years[5]. However, another asymmetry was revealed when the angular dispersion of the group of virtual poles from the Pacific hemisphere was shown to be significantly lower than that for the opposite hemisphere[4]. It has been realized for the past 20 or 30 years that the non-dipole field in the Pacific is lower than elsewhere, and it has been suggested that this might be a permanent feature of the field[7]. Furthermore, palæomagnetic directions for the Hawaiian lava flows are said to exhibit less scatter than usual for rocks of similar age and type from elsewhere[8].

By rotating the present field through 360° as described here, we cannot detect sectorial differences in angular dispersion, but this might be done by rotating it through a smaller angle which should be large enough to contain a sample of the non-dipole field representative of that likely to exist at a particular place with the passage of time, that is, it should contain parts of more than one regional source. 60° has been chosen as a reasonable compromise so as not to smooth out sectorial differences too much. In order to obtain a rather better sample of the local non-dipole field than by simply rotating it through 60°, virtual poles have been formed into groups

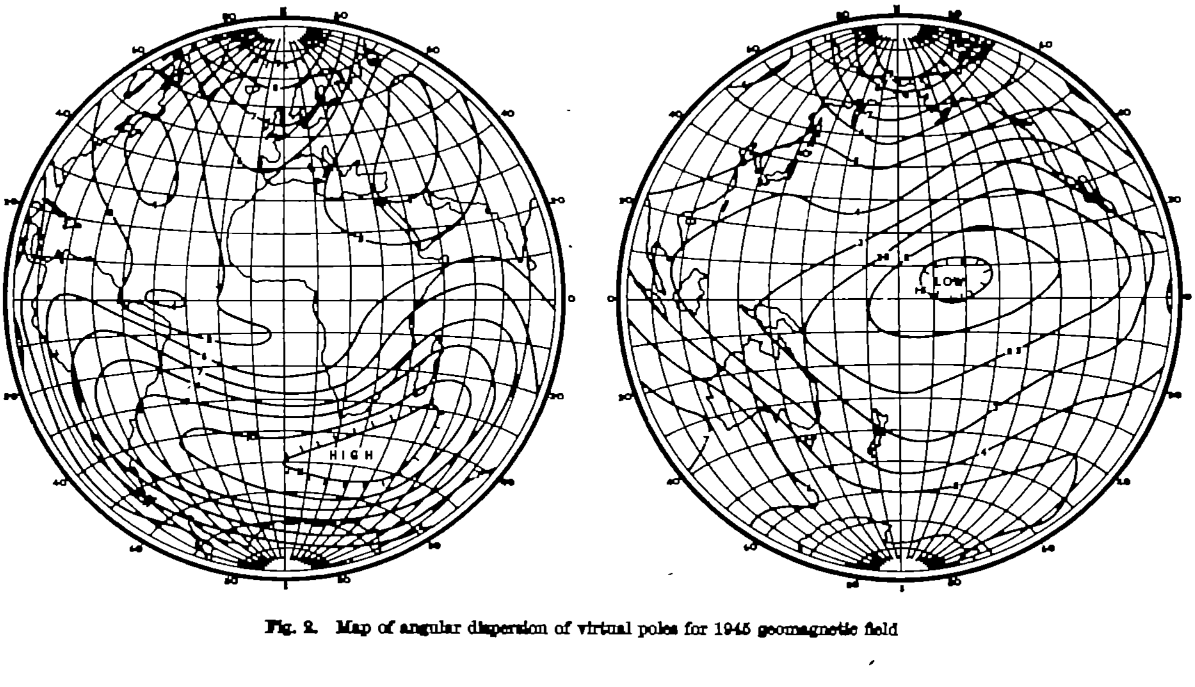

Fig. 2. Map of angular dispersion of virtual poles for 1945 geomagnetic field

lying within small circles of radius 30° described about the place for which the angular dispersion is being estimated. This has been done for all points on a 10° latitude-longitude grid. The angular dispersions so computed vary from less than 1·5° to more than 11° and a contour map is shown in Fig. 2. The map has 3 main features: (1) a region of low dispersion in the Pacific centred at 6° N., 165° W.; (2) a region of high dispersion just to the south of South Africa at about 45° S., 30° E.; (3) a region of high dispersion around the present north pole.

Whether these features are permanent, perhaps related to differences in conductivity in different parts of the mantle, might be revealed by computing the palæomagnetic angular dispersions of virtual poles from mean directions of magnetization of individual Quaternary lava flows within suites of flows from a world-wide distribution of sites. Although a considerable amount of palæomagnetic work has been done on Quaternary lavas, the data have not been presented in terms of mean lava flow directions. More systematic studies with the main object of determining the palæomagnetic angular dispersions due to past geomagnetic fields are necessary.

It is reasonable to suppose that sources of the non-dipole field are equally likely to occur at any longitude near the core surface, the total number existing at any one time being limited by their diameter, which has been estimated at about 50° (ref. 9). To an observer on the surface the effective period of field changes due to these sources is given by dividing the period of westward drift[8], 1,800 years, by the number of non-dipole sources of the same sign occurring round a line of latitude, that is, about 2, giving a period of about 10^3 years. McDonald[10] estimates that the conductivity at the base of the mantle is about 400 ohm^{-1} m^{-1} and that it decreases slowly for the inner 1,500 km and then rapidly with increasing radius. This value is too low to explain a suggested attenuation of the changing non-dipole field under the Pacific. Even allowing for the exponential increase of conductivity with temperature of the semi-conducting mantle rock, it is easy to show that a temperature difference of nearly 1,000° is required to explain why the strength of the regional sources in the Pacific is one-tenth of those near Africa. Runcorn[11] has suggested that a layer of iron as yet unabsorbed by the core might be responsible, and by taking a period of 10^2 years and a conductivity of 10^7 ohm^{-1} m^{-1} for iron at the temperature and pressure near the base of the mantle he calculates that skin depth of this material is about 10 km. For a period of 10^3 years as suggested here, however, the skin depth becomes 30 km and the presence of such a layer of iron might be detectable by seismic methods. The iron must form a layer, for if it were distributed in the mantle material much more would be required to produce a given attenuation; for example, a random distribution of iron spheres of concentration 50 per cent would only increase the conductivity of the mantle by a factor of about 5 (ref. 12).

Starting from the supposition that the Earth accreted cold with iron and stony material rather uniformly distributed, Elsasser[13] has developed a hypothesis which explains how the iron in the mantle might have become asymmetrically distributed. Suppose that the Earth heated up at a fairly uniform rate due to radioactivity from an initial temperature of about 1,000° K. The melting-point would be first reached near the top of any homogeneous layer because the melting-point-pressure gradient for silicates is much steeper than the adiabatic gradient. The actual temperature gradient would not be very different from the latter. Thus the iron would fall towards the centre in the outer layers first of all, and as it fell it would be slowed down owing to an increase of viscosity with depth as the gap between the actual temperature and the melting-point of the silicates decreased. It would thus form a coherent layer which, as the material contained afterwards heated up further owing to continued radioactivity, would become gravitationally unstable, resulting in the formation of quite large drops. These would then fall to the centre forming the proto-core. One of Elsasser's most important conclusions is that horizontal motion of iron must have occurred at certain levels leading to the formation of much larger drops than those corresponding to the original accretion. The time taken to form a proto-core is estimated to have been less than 10^8 years and the time for a drop to fall 10^5 years. As such a drop fell through the almost fluid silicate material the general flow pattern of the latter would at first be nearly streamline, but since the viscosity of the mantle is con-

sidered to increase with depth, the inner portion would not have time to flow but would be pushed outward by the falling drop of iron as shown in Fig. 3.

The composition of the mantle would thus become asymmetrical, the material displaced to the antipodal point containing iron, while that above the drop lost most of its iron. The drop axis would then precess about the axis of rotation and spiral towards it. Further differentiation of the iron-free material would occur later, sial rising to the surface forming a primeval continent at one pole, antipodal to an ocean above a mantle region relatively rich in iron. Thus the possible presence of a layer of iron near the base of the mantle under the Pacific could be a relic of this primeval asymmetrical distribution of iron.

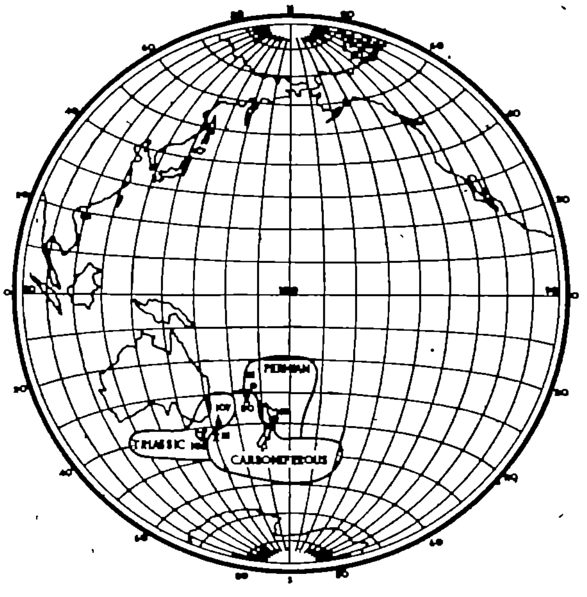

Fig. 6. Palæomagnetic poles determined from Australian rocks

By the end of the Pre-Cambrian, however, this primeval asymmetry might have decreased sufficiently so that the formation and settling of a new drop could topple the Earth relative to its axis of rotation. Although the difference in moment of inertia due to the absorption by the core of a drop, say, of diameter 500 km (that is, about ½ per cent of the volume of the proto-core) is only a few per cent of the difference in moments of inertia $(C - A)$ of the Earth's figure, it is more than enough to cause a movement of the pole because of the plasticity of the Earth[15].

An interpretation of the features shown by the map in Fig. 2 is now attempted using Elsasser's hypothesis. The region of low angular dispersion is close to the centre of depth of the Pacific ocean at 14° N., 161° W., and also to the mean palæomagnetic pole for North American rocks at 8·5° N., 163·5° W. (Fig. 4). The coincidence of the latter two features has previously been noted by Munk and MacDonald[14] and Elsasser[12], and they have suggested they might mark a primeval pole of rotation. The presence of the region of low angular dispersion supports this. In using the palæomagnetic data it is implied that North America has not moved relative to the Pacific basin during geological time.

It is possible that the region of high dispersion under the present north pole is due to the formation of a drop which cleared the mantle of iron beneath that region, hence allowing changes in the non-dipole field to pass through with less attenuation than in other regions.

The Permo-Carboniferous palæomagnetic south poles for west Europe, Siberia and North America lie fairly close to the region of high dispersion near South Africa (Fig. 5). The agreement in position is as good as can be expected: first, because the map (Fig. 2) is only an estimate of the angular dispersion of the geomagnetic field with time and hence of variations of conductivity in the mantle; secondly, because relative movement between the continents and that region could have occurred; and, thirdly, because of inaccuracies (of the order of 10°–15°) in some of the palæomagnetic data. If the position of the Permo-Carboniferous pole of rotation is marked in the mantle and revealed by the region of high dispersion, there is no need to postulate appreciable drift of South America relative to Africa since then to explain the Permo-Carboniferous glaciation. Fig. 5 shows that the few palæomagnetic poles available for rocks of this age from these two continents lie close to the group of palæomagnetic poles from the northern continents. Australia, however, must have suffered a considerable displacement since then because it is now situated a long way away from the 'high'. This suggestion is confirmed by the position relative to Australia of the palæomagnetic poles as shown in Fig. 6. The same applies to India; although there are no Permo-Carboniferous palæomagnetic data for that continent the position of the Cretaceous pole[3] is far from the 'high' and also far from the present south pole. For all other continents the Cretaceous pole lies between the Permian and present poles.

That the third important feature on the map in Fig. 2 lies on the present axis of rotation, strengthens the arguments for the hypothesis that the Pacific 'low' and the South African 'high' also mark ancient rotation axes. The large magnetic anomaly in the Arctic has been recognized for some time, but attempts[16] to explain it have relied on the supposed existence of ferromagnetic material in the crust.

If past axes of rotation are fossilized in the Earth's mantle, the consequences will be of great importance in geophysics, particularly in palæomagnetism, for in our interpretation of the data it will enable us to separate the effects of polar wandering (that is, a toppling of the Earth as a whole relative to the axis of rotation, which remains fixed in space) from those of continental drift. The arguments presented for the existence of such fossil axes of rotation are very speculative. It should be possible, however, as described above, to confirm or refute the ideas presented here by palæomagnetic investigations.

BEHAVIOUR OF THE GEOMAGNETIC FIELD DURING THE MIOCENE PERIOD IN SOUTH-EASTERN OREGON

By N. D. WATKINS
Department of Geophysics, Stanford University, Stanford, California

THE vast area and thickness of the lavas of the Columbia River Plateaux (Fig. 1, inset) offer an ideal opportunity to examine the behaviour of the Earth's magnetic field during the Tertiary era. During the summer of 1962 a palæomagnetic survey was made in part of south-eastern Oregon just north of the California and Nevada State boundaries (Fig. 1, inset). Previous work by Campbell and Runcorn[1] in northern Oregon and Washington revealed the existence of approximately equal numbers of normally and reversely magnetized lava flows of Miocene to Pliocene age, and Cox[2] found that normal and reversed Eocene lavas in north-western Oregon have, respectively, unusual north-east and south-west palæomagnetic azimuths.

The geology of the area investigated, which is part of the 'basin and range' province, has been summarized by Baldwin[3]. The region is more than 4,000 ft. in elevation and Steens Mountain rises to nearly 10,000 ft. The main characteristics exhibited are major northerly trending faults, which have produced exposures of up to 4,000 ft. of nearly flat-lying basalt flows, with some tuffs and andesites. A common and widespread petrological type is the Steens Mountain Basalt, which is a coarse-grained porphyritic diktytaxitic basalt[4].

Sedimentary beds with an Upper Miocene vertebrate fauna lap with a very slight unconformity on to the basalts[5]. Six flows at the top of sections *B* and *D* (Fig. 1) are separated from the underlying section by a thin wedge of sediments containing Upper Miocene vertebrates (G. W. Walker, personal communication), and these six flows are not discussed in this communication. In the western part of the area, Peterson[6] has described Lower Miocene silicic pyroclastic rocks. According to Walker[5], comparable rocks occur beneath the Steens type basalt, a few miles west of Lake Abert. Field relationships suggest that all the sections sampled are within these Lower to Upper Miocene age limits.

Seven hundred accurately orientated cores were collected from ten different sections (Fig. 1, *A–J*) ranging in vertical extent from 150 to more than 1,000 ft. The distance between the most widely separated sections is more than 100 miles. Measurement of the remanent magnetization has now been completed on at least one sample from each of 250 flows. Partial demagnetization of representative samples from all sections in alternating fields up to 800 oersteds generally reduced the intensity of magnetization to less than 10 per cent of the original intensity, but did not modify greatly the direction of

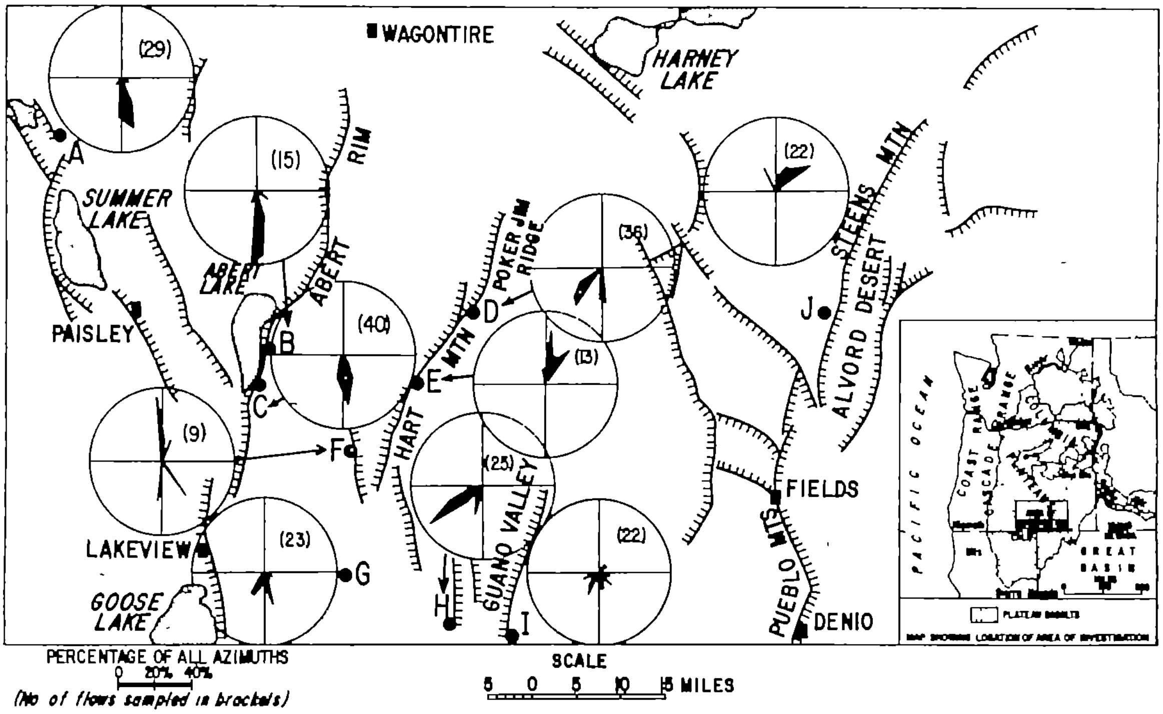

Fig. 1. Map with rose diagrams of palæomagnetic declinations in sections of Miocene lavas in south-eastern Oregon

magnetization. All the samples were subjected to demagnetization in an alternating field of 50 oersteds. At about this field the reversely magnetized specimens reached maximum intensity, indicating a complete removal of an unstable component parallel to the present field direction. A total of five samples with extremely high magnetic intensity, which may represent basalt remagnetized by lightning[7], have been disregarded. Twenty samples taken from baked soils associated with the lavas have magnetic directions in the same sense as those in the overlying lavas, lending evidence to the absence of the self-reversal type of magnetization observed in some lavas[8].

Eighty per cent of the flows possess a reverse magnetization. All the sections, excepting section *I*, show a close grouping of the directions of magnetization. Sections *F* and *I* possess both normally and reversely magnetized flows. The inconsistent directions in section *I* include a definite gradual transition between normally and reversely magnetized flows across a succession of six flows which may represent intermediate directions of the geomagnetic field during the process of reversal. Since this reversal is likely to accompany a decrease in intensity of the main dipole through a minimum to a maximum in an opposite direction, control of the ambient field by non-dipole sources would be expected to predominate close to this time, and hence a more rapid variation of magnetic direction would occur, resulting in a scatter of measured palæomagnetic directions.

The most significant result of the measurements is a systematic variation of the azimuth of the magnetic directions of each section from a north–south direction in the west of the area, to a north-east–south-west direction in the east of the area. These azimuths are plotted as rose diagrams in Fig. 1. Analysis of the directions of magnetization from the 84 flows measured in sections *A*, *B* and *C* would yield a virtual geomagnetic pole slightly west of present geographic north. This determination would contradict that made from sections to the east.

The systematic variation of palæomagnetic declination could be interpreted to be the result of differential tectonic rotation about vertical axes, subsequent to the original creation of parallel magnetic directions in these lavas of restricted relative age. This would be similar to Irving's[9] suggested explanation of Cox's[3] results from north-eastern Oregon. Such an interpretation cannot be accepted in the present investigation, however, when sections in the central part of the area are examined in detail.

It can be seen in Fig. 1 that a bimodal distribution of palæomagnetic azimuth is evident in sections in the centre of the area. Fig. 2 shows the magnetization directions for all flows from sections *D* and *E* in detail. A definite anti-clockwise swing of the palæomagnetic azimuth is observed suddenly in passing down the section from younger to older lavas. This has been observed in section *D*, where the flows are typical Steens Basalt, and are reversely magnetized; and in section *E*, which is composed of alternating coarse pyroclastics and fine olivine basalts, where the flows are normally magnetized. No sign of a significant geological hiatus between the critical flows is visible in the sections. Field relationships indicate that section *E* is older than section *D*. In section *H* (Fig. 3), the ambient magnetic field direction was relatively unchanging during the times when the youngest twelve flows were poured out. Flows 13–16 exhibit palæomagnetic directions which are flatter and more southerly than the younger flows. Then follows an oscillation of directions from southerly to westerly (17); westerly to southerly (18 and 19); southerly to westerly (20–25); and finally back to southerly (26).

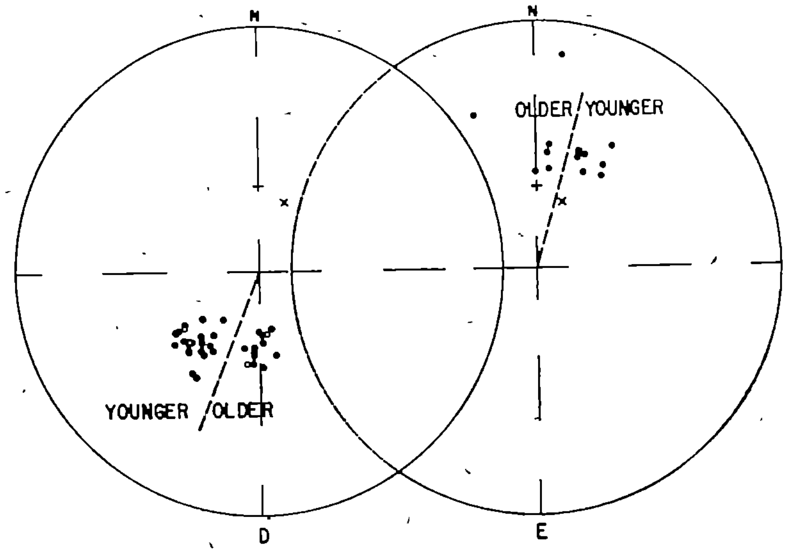

Fig. 2. Details of magnetic directions in sections *D* and *E*. Equal area projection. +, Direction of axially symmetrical dipole; ×, present geomagnetic field direction in south-eastern Oregon; ●, north-seeking polarity downward; ○, north-seeking polarity upward

Explanation of these dual palæomagnetic azimuths within single sections by differential tectonic movement is inconceivable. The cause of the systematic variation of declination across the area, as well as in single sections, is likely to lie in a variation of the ambient magnetic field, superimposed on the relatively small variation in age of the lavas investigated.

Whereas much laboratory work has been devised and carried out in recent years in order to eliminate unstable components of the measured magnetic directions in rocks and thus arrive at a true record of the ancient direction of the magnetic field, the exact meaning of these measured directions is far from certain. The working model of the origin of the Earth's magnetic field accepted for palæomagnetic purposes is that due to Elsasser[10]. Acceptance of this dynamo theory results in the averaging out of

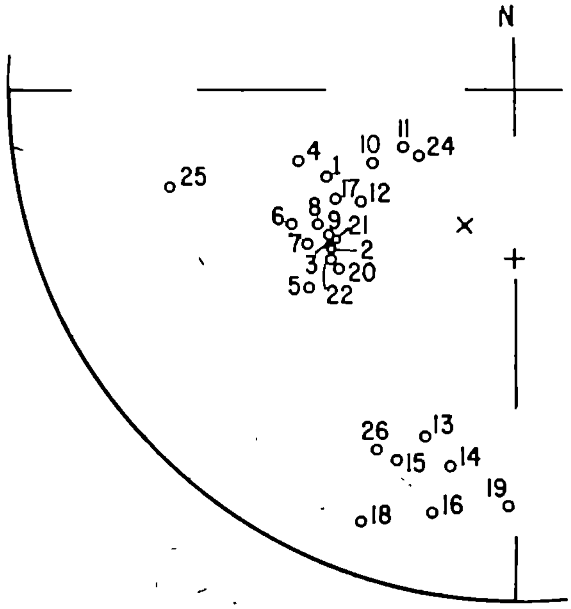

Fig. 3. Detail of change of magnetic directions in section *H*. Equal area projection. Numbers refer to flow, increasing in age with increasing number

○, North seeking polarity upward, +, direction of axially symmetrical south-seeking dipole field in south-eastern Oregon; ×, present south-seeking geomagnetic field direction in south-eastern Oregon both the main dipole and the non-dipole components of the magnetic field to the Earth's rotation axis if measured directions cover a long period of time[11], although it should be noted that movement of the main dipole has not yet been observed directly[12]. Exactly how many lava flows need to be sampled to be able to cancel out non-axial dipole components is a matter of considerable conjecture. Doell and Cox[13] suggest that sections of more than fifty flows in Hawaii may have accumulated in periods of time so short that the non-axial dipole components do not average out to the spin axis, or alternatively, non-axial dipole components persist for times long enough for the accumulation of relatively thick sections. The latter possibility is emphasized in an analysis of the present field by Cox[14], who has shown that the non-dipole component of the geomagnetic field is almost entirely absent from much of the Pacific Ocean.

Bearing in mind, then, that doubt exists about the details of the past behaviour of the geomagnetic field, the following explanations for the observations made of the Miocene lavas in south-eastern Oregon can be suggested:

(1) The lavas were poured out in rapid, but irregular, succession, and the movement of the measured magnetic directions represents movement of the ambient magnetic field in part of an ordinary change of the non-dipole field. The separation of the magnetic directions represents a small pause in the outpouring of the lavas.

(2) Alternatively, the lavas were poured out in regular succession over a fairly long period, and the separation of directions represents a sudden movement of the non-dipole, or possibly the dipole, field.

(3) The movement of the geomagnetic field, whatever its source, appears to have occurred in similar fashion during times when the ambient field was both north-seeking and south-seeking. Furthermore, the movement of the ambient field between two fairly well-defined directions may have been cyclic for at least a limited period.

Although further work on the basalts may reveal additional sets of magnetically normal and reversed zones which can be utilized for assisting in broad stratigraphical correlation, the preliminary indications of finer variations of the Miocene geomagnetic field in Oregon outlined in this article may permit a much more detailed correlation to be carried out.

I thank G. W. Walker (U.S. Geological Survey) for invaluable guidance during the geological work involved; Drs. A. V. Cox and R. R. Doell (U.S. Geological Survey) for generous loan of equipment, for guidance and review of the manuscript; and to Dr. G. A. Thompson (Stanford University) for help and encouragement.

This work is being completed under Air Force contract *AF*19(604)–8043.

NEWS and VIEWS

British Association for the Advancement of Science

Dr. N. C. Wright, deputy director-general of the U.N. Food and Agriculture Organization, has been appointed to succeed Sir George Allen as secretary of the British Association for the Advancement of Science as from October 1.

Sir George Allen was appointed secretary of the Association in 1954, having relinquished the vice-chancellorship of the University of Malaya two years previously. For much of his career he has been engaged in medical research and education in Africa and South-east Asia. He was principal of the College of Medicine, Singapore (1929–47), and president of Raffles College, Singapore, during 1932–34 and again during 1947–49, when he became vice-chancellor of the University of Malaya. He is at present chairman of the Council of Queen Elizabeth College (University of London) and vice-chairman of the Sponsors of the University of Kent. Due to his leadership, the Association now provides all the year round, and all over Britain, a service of lectures, junior meetings, and science fairs, which are doing much to interpret science to the public.

Dr. Norman Wright was the first director of the Hannah Dairy Research Institute. He served as chief scientific adviser to the Ministry of Food and then chief scientific adviser (food) to the Ministry of Agriculture, Fisheries and Food from 1947 until 1959, when he became deputy director-general of the Food and Agriculture Organization of the United Nations. He is a past general officer of the British Association and has been a member of its Council since 1950.

Personnel Moves in the Ministry of Aviation

In a written answer to a question in the House of Commons on December 20 regarding the number of civil servants in the Ministry of Aviation over the past ten years who had sought permission to take other posts within two years of retirement or resignation, the Minister of Aviation, Mr. J. Amery, said that applications by ninety-nine officers had been approved They included nine chief scientific officers, seven deputy chief scientific officers, seven senior principal scientific officers, six principal scientific officers, five senior scientific officers, one chief scientist, four senior experimental officers, six experimental officers, five assistant experimental officers, twenty engineers and two chemists.

The Post Office Engineering Research Station

In answering a series of questions in the House of Commons on December 18 regarding the siting of the Post Office Engineering Research Station, the Assistant Postmaster-General, Miss M. Pyke, maintained that working requirements necessitated a location nearer London than the areas of high unemployment. The staff of the Dollis Hill Research Station numbered 1,306, of whom 1,075 were established. The total included 57 scientific officers, 52 assistants (scientific), 92 experimental officers, 166 professional engineering grades, 145 assistant engineers, 76 drawing office staff, 255 technical officers and 205 technicians.

Aid to Economic and Social Progress of Developing Countries

In a written answer in the House of Commons on December 21, the Secretary for Technical Co-operation, Mr. D. Vosper, stated that he recognized the need, which had been emphasized to him by the Overseas Research Council, to sponsor research into problems which impede the economic and social progress of developing countries, both independent and dependent, as part of Britain's technical assistance effort. It was his intention, subject to the approval of Parliament, to provide separately in the Estimates of his Department for the support of research in and for overseas countries, who may welcome this form of aid, and such assistance would be available to any countries with which Britain had technical assistance arrangements. It would not be restricted to dependent territories, as under the terms of the Colonial Development and Welfare Acts. Funds previously available under the present Act for this proposal would be merged in the new provision, and an advance of £950,000 would be made from the Civil Contingencies Fund to cover expenditure between now and the approval of a Supplementary Estimate shortly to be presented to Parliament.

Dragon High-Temperature Reactor Agreement Extended

THE agreement extending the Organization for European Co-operation and Development's *Dragon* high-temperature reactor project to March 31, 1967, has now been approved and signed by all the participants in the project. Under the agreement, the total duration of the project is extended from five to eight years and the original £13·6 million budget is increased to £25 million. The main objective of the extended programme is "to provide the Signatories with information leading to the design of an economic land-based, gas-cooled, carbon-moderated, high-temperature power reactor". The original *Dragon* agreement, concluded between the U.K. Atomic Energy Authority, the Austrian and Swiss Governments, the national atomic energy authorities of Denmark, Norway and Sweden, and the Euratom Commission (representing Belgium, France, Germany, Italy, Luxembourg and the Netherlands), covered a period of five years from April 1, 1959. The project is carrying out a programme of research and development in the field of high-temperature gas-cooled reactors, and is designing and constructing a reactor experiment to obtain practical experience of this type of installation. The *Dragon* reactor experiment is now at an advanced state of construction at the U.K. Atomic Energy Authority's Atomic Energy Establishment at Winfrith, Dorset, where the team has its own technical building and has already carried out extensive research and development. Fuel loading in the reactor is expected at the end of 1963.

Dust-explosion Hazards in Factories

THE danger of dust explosions in industry in general appears to be less widely appreciated than the danger of gas or vapour explosions, although the number of industries in which a dust-explosion hazard may exist has increased rapidly during the present century. This is of some concern to the Committee on Industrial Fires and Explosions of the Department of Scientific and Industrial Research and Fire Offices Committee Fire Research Board, who asked for a review of the literature of dust explosions in factories to be prepared. This has been carried out at the Safety in Mines Research Establishment as part of the programme of the Joint Fire Research Organization (Research Report No. 201: *Dust Explosions in Factories—a Review of the Literature*. By K. C. Brown and Dr. G. J. James. Pp. 67. Sheffield: Ministry of Power, Safety in Mines Research Establishment, 1962. 6*s*. 6*d*.). The review covers methods and conclusions of many investigations of dust explosions, especially in connexion with the hazard in factories, up to June 1959. The subjects considered in the review include: combustion of single particles; forming dust clouds for experimental purposes; possible sources of ignition of dust clouds; studies of the propagation of flame through dust clouds; large-scale experimental work on the venting of explosions and of preventing the spread of flame. There is an excellent summary of precautions that can be taken against dust explosions in factories, suggestions of a number of aspects of the subject that merit early investigation and a list of more than 230 references. This critical review is far from the dry report it might have been. It is an important contribution to the subject of dust-explosion hazards and deserves wide circulation and publicity among those interested in the scientific and the practical industrial aspects of the problem.

Preventing Accidents in the Factory

EVERY year nearly 200,000 serious accidents occur in industry. Employers have legal and moral obligations to prevent accidents, but effective action towards accident prevention also needs co-operation from the man on the shop floor. To help employers in securing such co-operation from their workers, the Royal Society for the Prevention of Accidents has published a new booklet entitled *This is Your Life*, which states in simple, direct language how workers can help to prevent accidents to themselves and their fellow workers (Pp. 16. London: Royal Society for the Prevention of Accidents, 1962). Designed for distribution by employers to their workers, the booklet is written with a light touch and is illustrated with cartoons. It contains much sound advice on such highly practical matters as dressing for the job, safe operation of machines and tools, fire precautions, electrical hazards, personal hygiene, good house-keeping in the factory, first aid, and the avoidance of practical joking. In connexion with the last-named, there is a timely warning about the dangers of playing about with compressed air lines. Falls are a frequent cause of accident, and this danger is stressed in the booklet with appropriate illustrations.

Supplementary Letters of Sir Joseph Banks

IN December 1958 the Trustees of the British Museum (Natural History) published *The Banks Letters*, in which more than 7,000 letters were calendared of Sir Joseph Banks, the English naturalist (1743–1820). A number of further letters have now become available, and of the 139 letters summarized in a recent publication there are four important series, namely: (1) 38 letters from Banks to the antiquary, Francis Douce, in the Bodleian Library; (2) 28 letters from Banks to the second Earl Spencer, which are preserved in the Muniment Room at Althorp, Northamptonshire; (3) 26 letters from Banks to Dawson Turner in the Library of Trinity College, Cambridge; and (4) 16 letters from Banks to Matthew Flinders and his wife, now in the possession of Miss A. Flinders Petrie (*Bulletin of the British Museum (Natural History)*. Historical Series. Vol. 3, No. 2: *Supplementary Letters of Sir Joseph Banks*. Edited by Warren R. Dawson. Pp. 41–70. London: British Museum (Natural History), 1962. 8*s*.). Several letters are included from copies of which the originals are in American libraries; there is also a small series relating to the appointment of a chaplain to Banks while holding the office of High Sheriff of Lincolnshire in 1794, which were originally in the Evidence Room at Revesby Abbey. The remainder are miscellaneous in character, and among them are ten letters which were inadvertently passed over when *The Banks Letters* was in preparation. The publication contains a summary of each of the various groups of letters.

Comparative Efficiency of Indexing Systems

THE *Report on the Testing and Analysis of an Investigation into the Comparative Efficiency of Indexing Systems*—an investigation supported by a grant to Aslib by the National Science Foundation—is essentially for the specialist (Pp. 305. Cranfield: Aslib Cranfield Research Project, College of Aeronautics Library, 1962). After outlining the main test programme of this Aslib Cranfield Research Project, Mr. C. W. Cleverdon gives the results of the main test, the statistical analysis and analysis of failures and some results in testing existing indexing systems. Although he comments briefly on the results of the whole investigation and discusses briefly basic problems in retrieving information, from the point of view of the general reader or scientist this report adds little to the interim report already noted in *Nature* (189, 359; 1961).

Nonconventional Technical Information Systems

THE third of a series of reports on *Nonconventional Technical Information Systems in Current Use*, issued by the National Science Foundation, describes 87 such systems from 73 different organizations, six of whom reported two systems each, one three, and one seven (No. 3. NSF–62–34. Pp. xx + 209. Washington, D.C.: National Science Foundation, 1962). About half the organizations are new to the series, and three systems outside the United States are included. As in previous reports, the information is arranged under three main headings: systems which store references; systems which store data; and systems which produce general search aids. Comments on the compilation are invited and also information on other systems for possible inclusion in future reports.

The U.S. Office of Aerospace Research

Bulletin No. 15, September 1962, *NSF* 62–17, *Scientific Information Activities of Federal Agencies*, issued by the National Science Foundation, the first of four bulletins to deal with the U.S. Air Force, describes the activities of the Office of Aerospace Research, which is responsible for most of the basic research carried out or sponsored by the Air Force. Besides describing the various organizational units, the *Bulletin* includes information on the various fields of research, the progress being made and the types of publication issued.

A New High-sensitivity Colorimeter

A NEW Unicam *SP*. 1300 colorimeter, made by Unicam Instruments, Ltd., Cambridge, has a technical specification which incorporates many of the latest advances in colorimetry. Outstanding features include: (*a*) autofill cell—automatic system of filling and emptying cells, saving time and avoiding spillage (minimum volume of 10-mm glass sample well—2 ml.); (*b*) single lever control for three stages of analysis; (*c*) instant selection of filters by rotation of filter disk. Initially introduced with a series of sixteen clinical methods, the *SP*. 1300 is equally suitable for a very wide range of colorimetric analyses. The instrument will be supplied complete with a multiring binder containing operating instructions and methods of analysis for sixteen separate clinical determinations (other 'method sheets' will be made available to the users within a short space of time). The styling of this new Unicam instrument will fit well into the modern laboratory. It is compact, sturdy and easily transportable.

Ground Reflexion Interference Patterns

THE purpose of the National Bureau of Standards Monograph 38, issued on April 2, is to give the results of a detailed computation of ground reflexion interference patterns in the lower ionosphere at VHF over a spherical earth (*Radiation Patterns in the Lower Ionosphere and Fresnel Zones for Elevated Antennas Over a Spherical Earth*. Pp. iii + 128. Washington, D.C.: Government Printing Office, 1962. 70 cents). The computations cover parallax, tropospheric refraction and defocusing, spherical divergence, and near horizon diffraction. From the patterns, three antenna-siting parameters—the antenna height and elevation angle for placing the maximum of the first lobe at the path midpoint (called the lobe alignment height); the distances from the antenna to the edges and the quarter-wave contour of the first Fresnel zone on the Earth's surface; and information for the determination of effects of obstacles located in the first Fresnel zone—have been computed. The antenna height-gain function calculated from the results has been previously published (*Institute of Radio Engineers Transactions on Communications Systems CS*–8, 14–19; March 1960). The function shows that the optimum height is lower than the lobe alignment height and that a broad range of lower heights is essentially equivalent in gain to the lobe alignment height. The results presented in the monograph refer to an ionospheric scattering layer height of 85 km at frequencies of 30–55 Mc/s, which have been found to be the most useful values. They correspond to computed path lengths of 1,000–2,400 km. Two refractivities representing 'standard refraction' and temperate over-water or tropical 'wet' refraction were used. The monograph contains some hundred graphs, and in the appendixes lobe alignment antenna heights and other data, together with symbols and equations, are tabulated and a mathematical discussion of the lobe shift is given.

Farm Buildings Research

A BIBLIOGRAPHY, *Farm Buildings Research*, was issued by the Agricultural Research Council in 1958, covering publications of the previous three years. The first supplement to Part I of the general bibliography, covering publications of the three years ending in 1961, and also items omitted from the previous issue, has recently been published (Pp. 69. Agricultural Research Council, 1962. 4*s*.). This deals with buildings for pigs and provides a brief annotation for each reference quoted. An author index to the references is included.

Animal Disease in Israel

THE reports of the Veterinary Department in Israel for 1959 and for 1960 were published in Hebrew, but a report in English has now been issued for both years. Israel is inevitably an important area so far as the field of animal diseases is concerned. With its very central situation on certain travel routes between East and West and with some extensive terrain in its vicinity with, perhaps, less well-developed veterinary services, opportunities can occur of certain infective diseases to pass into regions that might be danger areas to other countries. With its strong scientific outlook Israel is a source of strength, in that new introductions of spreading disease are likely to be detected at an early stage, with quick introduction of control measures. In recent years, African horsesickness, as an escape from Africa, has been the cause of great losses as far afield as India—Israel being a stepping-stone in its progress. Bluetongue of sheep has similarly escaped from Africa and spread quite disastrously in recent decades. Similarly, African swine fever, caused by a virus different from that of the well-known swine fever, has invaded European countries with serious results, though, fortunately, active control measures have limited the risk to all but a few countries. Details are given of the activities in Israel for dealing with thirty-five scheduled diseases of mammals and with scheduled poultry diseases—the diseases given special attention in all countries because of particular liability to spread. The Government veterinary field service is handicapped by a serious lack of manpower. Rabies occurred from 1948 onwards in animals, including, as well as domestic animals, jackals, foxes, hyenas, wolves and a mongoose. There were reports of 69,995 persons being bitten, and 11,588 were given anti-rabies treatment.

Natural History of the British Solomon Islands

THE fourth volume of the scientific results of the joint Danish (1951) and British Museum (Natural History) (1953) expeditions to Rennell Island has been published under the general editorship of Torben Wolff (*The Natural History of Rennell Island, British Solomon Islands*. 4: (Invertebrates, Pars; and addition to Vertebrates). Pp. 120 + 18 plates. Copenhagen: Danish Science Press, Ltd. Published by the University, Copenhagen; and the

British Museum (Nat. Hist.), London, 1962. 35 Danish Kr.). Among the articles is one by J. E. Hill describing a little-known fruit-bat from Rennell Island. Diana Bradley has examined additional records of birds from Rennell and Bellona Islands, and Edward O. Wilson the ants of Rennell and Bellona Islands. Other articles include one by Carlton M. Clifford and Daniel Sohenshine on a new bat-infesting *Ornithodoros* (Ixodoiea, Argasidae) of the sub-genus *Reticulinasus* Schulze, 1941, from Rennell Island; J. Gaud on the bird parasites of Rennell Island, *Sarcoptiformes plumicoles* (Analgesoidea); J. P. Harding on *Mungava munda* and four other new species of ostracod crustaceans from the stomachs of fish; T. G. Howarth on *Rhopalocera* of Rennell and Bellona Islands; J. Balfour-Browne on Coleoptera from Rennell and Bellona Islands; R. T. Thompson on Curculionidae from Rennell and Bellona Islands; and Paul E. S. Sjalley on *Pyraloidea* from Rennell and Bellona Islands.

Deer Mouse in California

CALIFORNIA'S deer mouse is equally at home in mountains two miles above sea-level as at, for example, Death Valley, 200 ft. below sea-level. It is not known whether there is a fundamental difference in the physiology of the high-level as compared with the low-level mouse, or whether the differences are a matter of individual acclimatization. The mountain-top mice are heavier than the others, but they have relatively smaller adrenal glands. According to Dr. Raymond J. Hook, of the University of California, they have, as might be expected, larger hearts (*The Sciences*, 2, No. 6; August 15, 1962). Transplanted to lower altitudes, however, the already sluggish mountain-top mice lose 50 per cent of their endurance in the tread-mill test. The low-altitude mice also lose half their endurance when working at 12,000 ft. The decrease in efficiency when the mountain mice are brought to sea-level may be the result of 'oxygen drowning'—a not very well defined malady that is thought to have caused the deaths of some Peruvian Indians who left their homes at the turn of the century to work as servants in sea-level cities. To determine whether the differences in the mice are genetic, or merely the result of acclimatization, Dr. Hook is planning to raise litters at both altitude extremes, then move half of each crop of young deer mice to the opposite regions. His present expectation is that the mice will prove to be an adaptable species, adjusting themselves readily to environmental extremes.

The Institute of Biology

AT the fourteenth annual general meeting of the Institute of Biology, held on January 10, the following officers and members of Council were elected: *President*, Prof. G. E. Blackman; *Vice-Presidents*, W. H. Dowdeswell and Prof. I. A. Preece; *Honorary Secretary*, Dr. L. Broadbent; *Honorary Treasurer*, W. V. Harris; *Council Members*, K. G. Brocklehurst, Dr. J. A. Freeman, Dr. H. C. Gough, Prof. O. V. S. Heath and A. T. Thompson.

The Leopoldina German Academy of Sciences : Elections

THE Deutsche Akademie der Naturforscher Leopoldina, Halle, recently elected the following new members in the sections indicated: *Astronomy*, Prof. A. Unsöld (Kiel); *Chemistry*, Prof. F. Feher (Cologne); *General Biology*, Prof. J. Brachet (Brussels); *Physiological Chemistry*, Prof. J. Heller (Warsaw); *General Pathology and Pathological Anatomy*, Prof. J. Baló (Budapest) and Prof. Ilona Banga-Baló (Budapest); *Ophthalmology*, Prof. G. B. Bietti (Rome) and Prof. A. Bangerter (St. Gallen).

The Iron and Steel Institute

THE following elections to the Council of the Iron and Steel Institute have been announced: *President-elect*, F. B. George (managing director, Consett Iron Company, Ltd.); *Honorary Vice-presidents*, W. C. Bell (managing director, Iron and Steel Development, Stewarts and Lloyds, Ltd.), R. A. Hacking (metallurgical consultant to Richard Thomas and Baldwins, Ltd.), Sir Robert Shone (director-general, National Economic Development Council), C. H. T. Williams (chairman, Park Gate Iron and Steel Company, Ltd.); *Vice-presidents*, W. F. Gilbertson (assistant managing director, (production), Richard Thomas and Baldwins, Ltd.), Lt.-Com. G. W. Wells (chairman, Appleby-Frodingham Steel Company, and managing director (production), the United Steel Companies, Ltd.); *Members of Council*, R. W. Evans (director and general manager, Steel Division, the Steel Company of Wales, Ltd., Abbey Works), G. Foster (managing director (production), Dorman Long (Steel), Ltd., and director, Dorman Long and Company, Ltd.), L. R. P. Pugh (managing director, Guest Keen Iron and Steel Works, Cardiff).

Paul Instrument Grants Fund

THE Paul Instrument Fund Committee has made grants as follows: £1,550 to Dr. S. Evans, senior assistant in polar research, University of Cambridge, for experimental work in the Arctic, in continuation of the grant of £2,736 which was made in 1962 for the development of an instrument for measuring the depth of continental ice sheets by a radar technique; £3,000 to Prof. J. McMichael, professor of medicine in the University of London and director of the Department of Medicine, Postgraduate Medical School of London, for the development of a miniature electromagnetic flowmeter; £2,600 to Mr. J. Rawcliffe, lecturer in electrical engineering, and Prof. C. Adamson, professor of electrical engineering, in the Manchester College of Science and Technology, for the construction of a differential quartz thermometer. The Paul Instrument Fund Committee, composed of representatives of the Royal Society, the Institute of Physics and the Physical Society and the Institution of Electrical Engineers, was set up in 1945 "to receive applications from British subjects who are research workers in Great Britain for grants for the design, construction and maintenance of novel, unusual or much improved types of physical instruments and apparatus for investigations in pure or applied physical science".

The Oliver Memorial Award for Work in Blood Transfusion

THE Committee of the Oliver Memorial Fund announces that it will make the fifteenth annual Award of £50 and plaque to any British subject whose original work or service in the field of blood transfusion is considered to be an outstanding contribution to the science, organization or donor service aspect of this subject. The Committee welcomes communications directing its attention to suitable candidates, and, in accordance with the rules, the Award this year will be restricted to members of the medical profession. These must be submitted by March 31, and should be sent to the honorary secretary, Mrs. F. E. Bedborough, 105 New Park Avenue, Palmers Green, London, N.13.

Mass Spectroscopy

A SHORT course of five lectures on "Mass Spectrometry" is to be held at Battersea College of Technology, during January and February. The lectures will be held on Thursday evenings beginning on January 24. The course is under the direction of Mr. G. R. Parlett. The topics to be included are the introduction and theory, medical, organic chemistry and metallurgical applications and instrumentation; speakers will come from both university and industry. Further information and application forms can be obtained from the Secretary (Spectroscopy Courses), Battersea College of Technology, London, S.W.11.

Plant Pathogens in Soil

AN international symposium, "Factors Determining the Behaviour of Plant Pathogens in Soil", has been organized by the National Academy of Sciences–National Research Council Committee on Biological Control of Soil-borne Plant Pathogens. It will be held at the University of California, Berkeley, during April 7–13, 1963. Because the objective of the symposium is primarily to facilitate discussions between active workers in this field, participation will be by invitation. Invitations have now been issued. Those who are actively studying biological control of soil-borne plant pathogens and who would like an invitation can apply to Dr. W. C. Snyder, chairman of the NAS–NRC Committee, Department of Plant Pathology, University of California, Berkeley 4, before March 15, 1963.

University News :

Belfast

THE following appointments to lectureships have been announced: Dr. T. Williams (light electrical engineering); A. H. Garmany Love (medicine); C. W. R. McCreary (mycology and plant pathology).

Birmingham

THE following titles have been conferred: *Professor*, Dr. P. L. Krohn (endocrinology). *Reader*, Dr. R. L. Riddiford (high-energy physics); Dr. Anita Mandl (reproductive physiology); Dr. E. H. Ashton (primate anatomy); Sir Francis Knowles (comparative endocrinology); Dr. J. B. Finean (molecular biology). The following appointments have been announced: *Lecturer*, Dr. Bertha Singer (physiology). *Research Fellow*, R. F. Cheeney (geology); J. A. McCracken (physiology); Dr. H. S. H. Sherratt (medical biochemistry and pharmacology); Dr. E. F. Marshall (experimental neuropharmacology).

Borough Polytechnic

IN view of the fact that the advanced work in the Borough Polytechnic, London, S.E.1, is increasing rapidly session by session, both in volume and complexity, the former Department of Electrical Engineering and Physics is to be divided into two parts—one a separate Department of Physics under the headship of Mr. A. J. L. Collinson, and the other the Department of Electrical Engineering which will continue with Mr. V. Pereira-Mendoza as head. In addition, the former Department of Chemistry and Food Technology has been divided. One portion, known as the Department of Chemistry and Chemical Technology, will function under the headship of Dr. S. Cotson, and the other, designated the Division of Food Science and Technology, will be under the headship of Dr. D. B. Smith. In addition to this reorganization, all work in science and engineering up to and including Ordinary National Certificate Level will be grouped in a General Science and Engineering Section in charge of Mr. L. M. Clark and Mr. C. E. T. Maguire.

The College of Aeronautics

THE following appointments have been announced: J. Murdoch, senior research fellow in the Department of Production and Industrial Administration, to the post of senior lecturer, with effect from January 1, 1962; Dr. P. L. B. Oxley, lecturer at the Manchester College of Science and Technology, to the post of senior lecturer in the Department of Production and Industrial Administration, with effect from July 1, 1962; A. Battersby, senior technologist, British Petroleum, Ltd., to the post of senior organizer in the Work Study School, with effect from September 1, 1962; G. S. Ram, senior scientific officer, National Aeronautical Laboratory, Bangalore, to the post of research fellow in the Department of Aerodynamics, with effect from May 1, 1962; R. J. L. McLaren, engineer, English Electric Co., Ltd., to the post of research fellow in the Department of Aircraft Propulsion, with effect from September 1, 1962.

Leeds

THE following appointments to lectureships have been announced: Dr. M. P. Crosland and J. E. McGuire (history and philosophy of science in the Department of Philosophy); Dr. J. G. Shoesmith (bacteriology); J. W. T. Richards (psychology).

London

THE title of professor emeritus of western asiatic archæology in the University has been conferred on Prof. M. E. L. Mallowan. (Prof. Mallowan was professor of western asiatic archæology at the Institute of Archæology from 1947 until 1962.) The title of professor of molecular biology in the University has been conferred on Dr. M. H. F. Wilkins, in respect of his post in the Department of Biophysics at King's College. Dr. L. B. Strang, senior lecturer at the Institute of Child Health, has been appointed to the readership in pædiatrics tenable at University College Hospital Medical School.

Nottingham

THE title of professor has been conferred on John Edward Adkins, at present reader and head of the Department of Theoretical Mechanics, who is well known for his work on non-linear continuum mechanics with special reference to non-linear elasticity.

Southampton

AN independent Institute of Sound and Vibration Research is to be established within the Faculty of Engineering with effect from October 1. The first director of the Institute will be Prof. E. J. Richards, at present professor of aeronautics and astronautics in the University

Announcements

MR. P. M. HOLLINGSWORTH has been appointed deputy chief engineer of British Insulated Callender's Cables, Ltd. Mr. Hollingsworth joined the former British Insulated Cables Ltd. in 1928 after graduating from the University of Liverpool. In 1938 he went to Johnson and Phillips, Ltd. as manager, Cable Test and Research Department. He rejoined B.I.C.C. in 1954 as chief engineer, Power Cables Division, afterwards becoming assistant chief engineer.

AT the annual general meeting of the Photobiology Group, held at the Institute of Ophthalmology, on October 19, Dr. L. R. Fisher of the National Institute for Research in Dairying, Reading, was elected honorary secretary in succession to Dr. D. Vince. Dr. H. J. A. Dartnall of the Institute of Ophthalmology was elected as chairman to succeed Prof. N. Millott.

THE pharmaceutical business operated by the Distillers Co. (Biochemicals), Ltd. has been transferred to the Eli Lilly Group of Companies as from January 1. The business is being operated by a new company named Dista Products, Ltd.

A SHORT course for graduates on "Flow Processes in Polymeric Systems" will be held at the Bradford Institute of Technology during March 8–9. Lectures to be delivered will include: modern trends in rheology (Prof. K. Weissenberg); rheology of polymer melts (Dr. E. R. Howells); rheology of concentrated polymer solutions (Dr. D. W. Saunders); measurements of flow properties in polymeric systems (Dr. M. F. Culpin); rheology of surface coatings (T. R. Bullett); viscosity–temperature relationships for polymer solutions (Dr. W. R. Moore). Further information can be obtained from the Registrar, Bradford Institute of Technology, Bradford 7.

THE jubilee meeting of the British Ecological Society will be held at Queen Elizabeth College, Campden Hill Road, London, W.8, during March 28–31, and not March 8–31 as announced in *Nature*, 196, 1271; 1962.

THE tenth international symposium on "Combustion", organized by the British Section of the Combustion Institute, will be held at the University of Cambridge during August 16–21, 1964. Further information can be obtained from Dr. W. G. Parker, Department of Chemistry, College of Advanced Technology, Gosta Green, Birmingham 4.

THE BRITISH COKE RESEARCH ASSOCIATION

THE annual report for 1961 of the British Coke Research Association, Chesterfield, is noteworthy not only for the review of progress in all aspects of the Association's recent activities but for special mention of a number of new ventures which were begun during the year*. Support by the Department of Scientific and Industrial Research had enabled the Association to provide member-organizations with several new services in the field of technical information, the purpose being to further the effect with which the results of research can be applied in industry. The new developments have covered briefly the establishment of a more comprehensive abstracts service, improved technical liaison between the Research Centre and producers and consumers of coke, a field trials officer and a fully equipped mobile laboratory to demonstrate among other activities methods of sampling, analysis and testing of coke, and the assessment of smoke emission from coking plant. The provision of a mobile laboratory for plant trials under industrial conditions is becoming a most valuable instrument of technical advancement in a wide range of practice.

This Association is unique for the fact that it is the only co-operative research organization in the world that is devoted solely to the study of the production of coke and its associated problems. The Research Centre in Chesterfield has accordingly become a focal point for the industry. There is special interest in the fact that the Centre is capable of carrying out modern research on a large scale, as well as the fundamental and applied research that must remain the source of the basic ideas on which progress in many techniques associated with coking plant must depend. The result has been a growing flow of interested visitors from other technical organizations in Britain and overseas.

As to the achievements of the year and the use of the test plant in regard to the improvement in the quality of coke and yield of metallurgical plants, the investigations have been concentrated on the effect of variation of specific operating conditions. Thus the addition of breeze in the charge, pre-drying, the addition of wet or partially dried filter coke, the rate of carbonization and the use of high bulk density. The use of the 10-ton oven in evaluating with an established accuracy the relative merits of such variables defines, in effect, an optimum practice, which could not readily, by other means, be ascertained.

In respect of the fundamental studies of the structure and properties of coke an interesting preliminary investigation has been made of the potentialities of polarized light microscopy for the study of coke structure. The early indications are that the optical method utilized is probably more informative in respect of structural orientations of significance than some X-ray techniques, but that its application to technical cokes may be limited by the sampling difficulties. Investigations of magnetic data collected on a variety of cokes and carbons have given rise to tentative conclusions of significance in respect of the reactivity of coke. Thus the magnetic and probably chemical behaviour of high-temperature coke can be attributed, in part, to the excess or deficiency in the mobile electrons normally associated with the graphitic crystallites in the coke. These are influenced in their turn by the origin and temperature of formation of the coke.

The layman may be interested to learn that the subject of the tailoring of the domestic coke to suit the small boiler used for hot-water heating has been receiving important attention. Conclusions relative to the size, shape and ash content of the coke in this context inevitably have their effect on the character of the coke to be found in the market. Most favourable features appear to lie with the ½–1-in. coke.

Under the sponsorship of the Association are the liquid effluent studies carried out in the Houldsworth School of the University of Leeds. A particularly valuable service has been the biological assessment of coking-plant wastes in those cases where some form of treatment plant is envisaged. The biological treatment of spent liquor from ammonia stills is a relatively easy matter, but certain rogue liquids also produced in a by-product plant can do permanent damage to the activated sludge. These effects have been traced to the hydrogen sulphide and cyanide contents of the waste liquors.

In the Northern Coke Research Laboratory at Newcastle the research objectives included the study of the structure, reactivity and electron-spin resonance properties of carbons prepared from organic polymers. The maximum free-spin concentrations were shown for carbonization temperatures between 500° and 700° C. Two problems were revealed: (1) in the way in which the unpaired electrons were associated with the carbon structure; (2) in the effect of the heat-treatment temperature of the carbonized products on the observations made. Other experimental techniques would have to be considered in the final interpretation of the observations made, which could be of considerable interest from the point of view of reactivity. As the problem is looked at from the angle of the metallurgist in the manufacture of iron and steel it is a relatively simple matter to produce reactivity, but what is more frequently required, and difficult, is to produce unreactivity. To be able to understand the why and the wherefore is to go a long way towards solving the problem. Further, in respect of the domestic needs, the attainment and control of reactivity in respect of coke supplies is a most important matter, since it controls that most important requirement—the rate at which the fuel burns.

---

*British Coke Research Association. Eighteenth Annual Report for the year 1961. (Chesterfield: British Coke Research Association, 1962.)

FOREST PRODUCTS IN CHILE

IN the recently created Instituto Forestal* in Santiago, Chile, representatives of all Chilean forest products laboratories joined in a conference on the "Co-ordination of Forest Products Research" during August 30–31, 1962.

The Instituto Forestal commenced its activities in November 1961 as the result of an agreement between the Chilean Government and the United Nations (Special Fund and Food and Agriculture Organization). Under its draft statutes, its object is "to contribute to the promotion, development, and investigation of the forest resources and industries within the territory of this country [Chile]". It comprises four technical sections, namely, forestry, forest industries, marketing, and extension. Research on forest products is being undertaken in collaboration with established forest products departments in the various universities of the country, as the Institute does not have its own laboratory.

The purpose of the conference was to co-ordinate research on forest products in Chile, and to agree on a plan of co-operation, in order to encourage research projects of national importance.

---

* Postal address: Instituto Forestal, Casilla 3085, Santiago de Chile.

The research needs of the Chilean wood-using industry were presented by A. Pérez, the Institute's officer-in-charge of forest products research. He directed attention to the urgent necessity for applied research and education in the basic conversion processes such as sawmilling, veneer and plywood, preservation, seasoning, and pulping, as well as for fomenting auxiliary industries such as manufacture of adhesives. The Institute's Food and Agriculture Organization adviser on research, Dr. W. G. Kauman (senior research officer, C.S.I.R.O., Division of Forest Products, Australia; on leave of absence), pointed out that of the three main types of research, that is: (1) short-term problem solving; (2) determination of basic properties; (3) academic research, the second constitutes the most urgent task for the university laboratories, but that the third must be given due importance to ensure a future supply of professional and other academic staff.

Prof. G. Mittak, of the recently formed Austral University of Valdivia, emphasized the importance his laboratory is attaching to wood anatomy, in particular identification, and to drying of difficult *Nothofagus* species. For the Catholic University of Santiago, H. Ayarza presented a comparison of the mechanical strength of *Pinus radiata* determined on small clear specimens and on commercial sizes, and work on various timber joints and connectors. Research on timber in the Institute for Testing Materials in the University of Chile, Santiago, as outlined by H. Albala, is mainly concerned with mechanical strength of Chilean timbers. Due attention is being given to statistical design of the experiments, a factor which has been largely neglected in much of the past work in Chile. Nineteen species have so far been investigated. E. Cuevas presented work on timber physics and preservation in the Forest Engineering School of the University of Chile. Interesting results have been obtained on the frequency distribution of density in fifteen species, and correlations of other properties with density are being examined. E. Bluhm, of the University of Concepción, stated that his laboratory is concentrating on wood chemistry and pulp and paper, and reported a laboratory project on pulping by the nitric acid process. In the Technical University Federico Santa María of Valparaíso, forest products work so far has dealt with pulping, minor forest products and utilization of lignin. Prof. R. Ripa reported on an investigation of production of detergents from sulphonated lignin derivatives. Prof. J. Hirschmann, of the same University, gave details of a new professional course for timber and plastics engineers, now in its third year.

The participants agreed on a plan for co-ordinated research on forest products proposed by Dr. W. G. Kauman, of the Instituto Forestal, and resolved to work in close collaboration to counteract the difficulties created by the dispersion of facilities.

GAMMA-RAY STERILIZATION OF MEDICAL UTENSILS

THE world's first privately owned cobalt-60 irradiation plant designed specifically for medical purposes began continuous operation on November 10 at Johnson's Ethical Plastics Ltd., Slough. It is to be used to sterilize disposable, or single use, plastic hypodermic syringes. The only other plants which resemble it are the United Kingdom Atomic Energy Authority's experimental unit at Wantage, Berks., and a privately owned installation in Australia used for sterilizing goat hair. The plant at Slough was designed and constructed by H. S. Marsh Ltd., Reading, in collaboration with the United Kingdom Atomic Energy Authority.

The radioactive source which emits the sterilizing γ-rays consists of 120 cobalt rods which have become radioactive by treatment in a nuclear reactor at Calder Hall. The rods have a half-life of five years. The capacity is 50,000 curies, but provision has been made to measure the number of rods to a maximum of 720 with a possible rise to half-a-million curies. The cell in which the cobalt is loaded is a concrete block weighing some 700 tons, and occupying most of the space of the building of 2,500 sq. ft., which houses the plant.

The main object of the disposable or single-use syringes is to reduce or avoid the incidence of cross-infection. Gamma irradiation provides the safest and surest way of assuring sterility. The syringes are made of polystyrene, the grummets of surgical rubber and the needles of stainless steel. It is claimed that it is more economical to use disposable syringes than to wash and clean glass syringes, clean and sharpen needles, and sterilize them by orthodox methods. The present production and sales of disposable syringes is more than 12 million per annum.

At the inauguration luncheon held on November 9 in London the guest of honour was Sir Roger Makins, chairman of the United Kingdom Atomic Energy Authority, and it was announced that to mark the occasion of the opening of the cobalt-60 plant, the Medical College of St. Bartholomew's Hospital, London, had accepted a grant of £2,400 spread over three years made by Johnson's Ethical Plastics Ltd. The money is to be used by Prof. J. Rotblat in the Department of Physics to employ a radio-biologist as assistant in his radiation research.

RESPONSE OF AN ASTATIC MAGNETOMETER TO A CYLINDRICAL ROCK SPECIMEN

By J. L. ROY

Dominion Observatory, Ottawa

SPECIMENS of weakly magnetized rocks are often cut in cylindrical form for measurement with an astatic magnetometer. It will be shown here that the response of a two-magnet astatic system depends on the relative dimensions of the specimen, that is, on the ratio of height to radius. A knowledge of the nature of this response variation is important if, as is usually the case with weakly magnetized rocks, the largest possible deflexion for a given intensity of magnetization is required. The standard practice has been to use rock specimens in the form of thin disks. It is concluded that the height of cylindrical specimens should be comparable with their diameter.

The design theory and description of an astatic magnetometer can be found elsewhere[1-3]. In brief, the intensity and direction of magnetization of a specimen of magnetic moment p are measured by placing the centre of the specimen at a distance z below the axis of the lower magnet (of the magnetometer) and at a distance $x < z$ from the plane of magnetization of the magnetometer.

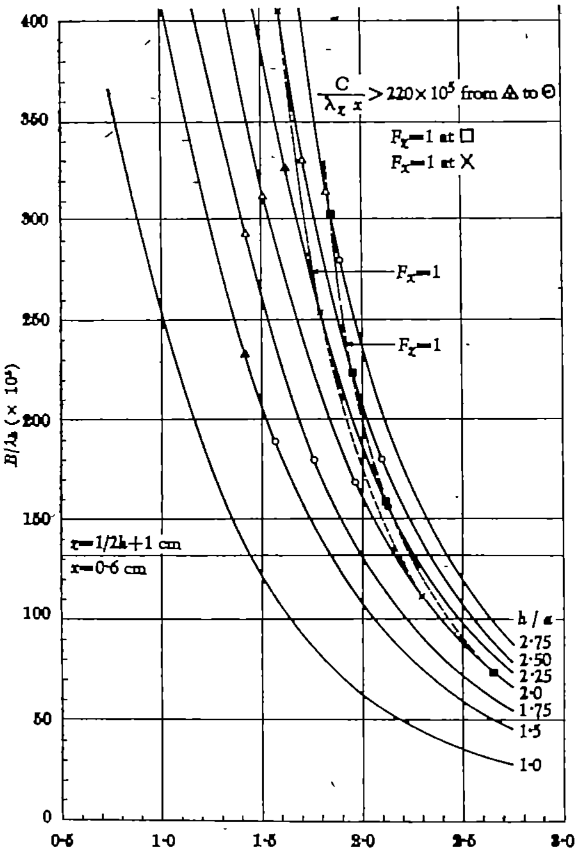

Fig. 1. Variation of B/λ_h with $z/a = v$ for given ratios $h/a = u$ calculated from equation (10)

It can be shown that, if the distance between the two magnets of the system is much larger than z, the vertical component p_z of the magnetic moment of the specimen is given by:

$$p_z = CH_1z^4/3x \quad (1)$$

H_1 is the field required at the lower magnet to produce a deflexion of 1 mm at a scale placed at a fixed distance from the instrument and is given in oersteds per mm deflexion. C is the linear deflexion in mm measured at the scale.

The horizontal component p_x perpendicular to the plane of magnetization of the magnetometer is given by:

$$p_x = B_x H_1z^3 \quad (2)$$

The horizontal component p_y parallel to the plane of magnetization is obtained by rotating the specimen through 90° in azimuth and is given by:

$$p_y = B_y H_1z^3 \quad (3)$$

and the total horizontal component $p_h = (p_x^2 + p_y^2)^{1/2}$ of the magnetic moment can be written:

$$p_h = (B_x^2 + B_y^2)^{1/2} H_1z^3 = BH_1z^3 \quad (4)$$

In the calculations of these expressions, it has been assumed that the dimensions of the specimen were small compared with the distance z. Very often, however, it is necessary, owing to the weak magnetization, to cut large specimens with dimensions comparable to z. Papapetrou, quoted in Blackett[1], has calculated the horizontal fields produced outside and near the vertical axis of a circular cylinder of radius a, height h and uniformly magnetized. The expressions obtained show that, if the geometrical centre of the specimen is placed at the same distance $(x^2 + z^2)^{1/2}$, with its axis vertical, the foregoing expressions can be used provided that equation (1) is divided by the correcting factor F_z and equations (2) to (4) are divided by $F_x(= F_y = F_h)$ where:

$$F_z = \frac{1}{6U}\left[\frac{1}{\{(1-U)^2+V^2\}^{3/2}} - \frac{1}{\{(1+U)^2+V^2\}^{3/2}}\right] \quad (5)$$

$$F_x = \frac{1}{2UV^2}\left[\frac{1-U}{\{(1-U)^2+V^2\}^{1/2}} - \frac{1+U}{\{(1+U)^2+V^2\}^{1/2}}\right] \quad (6)$$

$$U = h/2z \text{ and } V = a/z$$

Size and ratio of height to radius of specimen. If we define λ_h and λ_z as the horizontal and vertical intensities of magnetization of the specimen, we have (using the previous expressions):

$$B/\lambda_h = \pi a^2hF_x/H_1z^3 \quad (7)$$

$$C/\lambda_z = 3\pi xa^2hF_z/H_1z^4 \quad (8)$$

In general, these ratios should be made as large as possible so that large deflexions can be obtained from weak intensities of magnetization and so that the effects of artificial disturbances affecting the magnetometer, such as vibrations and drift, can be minimized.

We shall, then, investigate the manner in which these ratios depend on the dimensions of a cylindrical specimen.

If K is the vertical distance from the centre of the lower magnet to the upper surface of the specimen, then:

$$z = (1/2).h + K \quad (9)$$

The response ratios B/λ_h and C/λ_z can be expressed in terms of the quantities $u = h/a$, $v = z/a$ and K. Using these variables, equations (7) and (8) are written:

$$B/\lambda_h = \pi uF_x/H_1v^3 \quad (10)$$

$$C/\lambda_z x = 3\pi u\{v - (1/2).u\}F_z/H_1Kv^4 \quad (11)$$

In Figs. 1 and 2, B/λ_h and $C/\lambda_z x$ are plotted against v for fixed values of u, assuming $H_1 = 4{\cdot}7 \times 10^{-5}$ oe/mm defl. and $K = 1$ cm. For values of K other than 1 cm, equation (11) shows that the ordinates in Fig. 2 would have to be divided by K. For values of H_1 other than $4{\cdot}7 \times 10^{-5}$ oe/mm defl., the ordinates of both figures would have to be multiplied by $4{\cdot}7 \times 10^{-5}/H_1$.

Figs. 1 and 2 show that while B/λ_h increases indefinitely as v decreases, C/λ_z, for a given x, goes through a maximum as v is varied. Thus, while it is desirable to have both these ratios large, care must be taken to choose values of u and v which do not increase B/λ_h unduly at the expense of C/λ_z.

In Fig. 2, a line has been drawn at $C/\lambda_z x = 220 \times 10^5$ in order to form a comparison between values of B/λ_h and C/λ_z. The values of h/a and z/a for which $C/\lambda_z x = 220 \times 10^5$ are carried over to Fig. 1, where the corresponding values of B/λ_h are shown. If x is taken to be 0·6 cm (this value can be considered as the maximum permissible

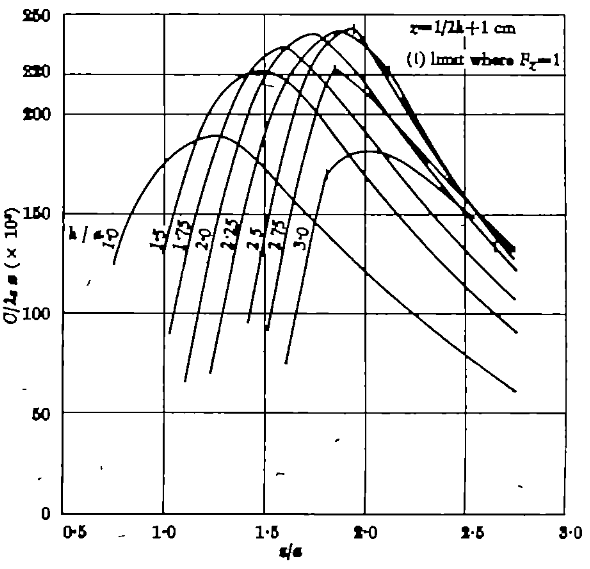

Fig. 2. Variation of $C/\lambda_z x$ with $z/a = v$ for given ratios $h/a = u$ calculated from equation (11)

value of x since the calculations are made under the assumption that x is much smaller than z which, in general, is of the order of a few centimetres), then $C/\lambda_z = 132 \times 10^5$ and a line is drawn in Fig. 1 showing this maximum value.

It is clear that, for any combination of u and v giving $C/\lambda_z = 132 \times 10^5$, we have:

$$B/\lambda_h > C/\lambda_z \qquad (12)$$

when $K = 1$ cm and $x = 0{\cdot}6$ cm. Furthermore, an increase of K to any value greater than 1 cm or a decrease of x to any value less than 0·6 cm will decrease C/λ_z proportionately (11). Although a reduction of K to a value less than 1 cm would increase C/λ_z, a damping disk beneath the lower magnet usually prevents a much closer approach of the specimen. Thus, the foregoing inequality holds for all practical values of K and x. It is concluded, therefore, that u and v should, in general, be chosen so that C/λ_z is close to its maximum possible value. Fig. 2 indicates that this condition can be fulfilled if:

$$1{\cdot}5 \leqslant h/a \leqslant 2{\cdot}75 \qquad (13)$$

and the appropriate value of z/a is chosen.

An exception to this rule might occur with a specimen for which B/λ_h and hence B is very small. In this case, it might be desirable to increase B/λ_h at the expense of C/λ_z in order that both B and C be large enough for accurate measurement. This could be done by increasing u and/or decreasing v. It should be noted, however, that the absolute dimensions of a specimen are given in terms of u, v and K by:

$$\begin{aligned} h &= 2uK/(2v - u) \\ a &= 2K/(2v - u) \\ z &= 2vK/(2v - u) \end{aligned} \qquad (14)$$

These relations show that h and a increase indefinitely as u approaches $2v$. Thus the process of increasing u or decreasing v cannot be carried beyond the point at which practical dimensions of the specimen are exceeded. Besides requiring large coring equipment and magnetic washing apparatus, large specimens might also be difficult to collect in the field.

It has been noted that optimum values of $u = h/a$ are, in general, such that the height is approximately equal to the diameter. It is clear from both figures that the use of thin disks leads to reduced response to both horizontal and vertical components of magnetization in the specimen.

Elimination of the correcting factors: F_z and F_x. Since F_z is required in equation (8) because the dimensions of the specimen are comparable to z, it is clear that F_z will tend towards unity if for a given ratio h/a z/a is made large enough.

The value of $v = z/a$ required to make F_z approximately equal to unity ($F_z > 0{\cdot}995$) has been calculated from equation (5) (for the various fixed values of $u = h/a$ considered here) and is shown in Fig. 2 by a short vertical stroke drawn across the curve of h/a used in the calculation. Any combination of h/a and z/a lying to the right of the curve which could be drawn through these strokes gives a value of F_z equal to unity. We see, then, that F_z will be equal to unity and, at the same time, $C/\lambda_z x$ will be larger than 220×10^5 if h/a is chosen so that:

$$2{\cdot}25 \leqslant h/a \leqslant 2{\cdot}75 \qquad (15)$$

with appropriate ratio z/a.

Similar calculations have been made for F_x and the results are shown in Fig. 1. Any combination of h/a and z/a lying to the right of the dashed line X give a value of F_x equal to unity. Now, carrying the combinations of h/a and z/a giving 'limit where $F_z = 1$' from Fig. 2 to Fig. 1, we find that, whenever h/a and z/a are chosen so that $F_z = 1$, then F_x is automatically equal to unity, since the curve of $F_z = 1$ lies to the right of the curve of $F_x = 1$.

We conclude, therefore, that it is preferable to cut a specimen according to the dimensions given by equation (15) since, besides obtaining the largest deflexions B and C, we also eliminate both correcting factors F_z and F_x.

In palæomagnetic work, the distance K is determined by the degree of non-uniformity of magnetization of the specimen and should be chosen large enough so that the error due to this inhomogeneity is negligible.

I thank Dr. E. R. Niblett for help with preparation of this manuscript.

CLASSIFICATION OF CALDERAS: 'KRAKATOAN' AND 'GLENCOE' TYPES

By Dr. G. J. H. McCALL
University of Western Australia, Perth

TWO short communications by Yokoyama and Tajima[1] and Yokoyama[2] have recorded the recognition of low and high Bouguer anomalies, centred on 'Krakatoan' and 'Glencoe' type subsidence calderas respectively. These two communications from Japan were of considerable interest to me, because I have examined a group of similar but smaller calderas in the central rift valley of Kenya.

I initially studied the 35 square mile subsidence caldera of Menengai[3,4]; striking similarities to Santorin and Aso[5] led me, at that time, to invoke a 'Krakatoan' mechanism. Later, however, a detailed study of the caldera was made (McCall, "Geology of the Nakuru–Thomson's Falls–Lake Hannington Area", awaiting publication, Geological Survey, Kenya) and the smaller (3 sq. miles) Kilombe caldera to the west of Menengai was briefly examined (McCall, unpublished results); the calderas of Suswa volcano to the south were also examined (McCall, unpublished results, investigation in progress in collaboration with C. M. Bristow) and these recent investigations together with a visit to Norway, where the Baerum cauldron, near Oslo[6,7], came to my notice, have led me to revise my earlier interpretation of the Menengai caldera, an interpretation which appears to have been too simple. Menengai closely matches the Baerum cauldron in shape, position and orientation in a meridional graben, in size, in the presence of narrow magmatic screens along the marginal fractures (vestiges of a ring feeder of trachyte-obsidian and pumice have now come to light in the south-east and southern margins of the caldera, following on the recognition of a much more completely preserved ring-feeder in the outer caldera of Suswa), and in the local repetition of the bounding fracture (evidenced in the case of Baerum by the repetition of the narrow syenitic ring-dykes, and in the case of Menengai by step-faulting in the caldera walls). It seems certain that Menengai represents the surface expression of a subsidence cauldron such as Baerum, the much lesser degree of erosion experienced by the Plio-Pleistocene structure of Menengai allowing for the preservation of the surface-levels, completely removed by erosion in the case of the Permian structure of Baerum. Menengai is then, primarily, a 'Glencoe' type subsidence caldera[8].

What then of the very real 'Krakatoan' characteristics of Menengai, the strong resemblance to Santorin and Aso, both in the form of the caldera and the characteristics of the associated eruptions ? Can it be that the 'Glencoe' mechanism is more commonly associated with calderas of subsidence than Williams in his well-known definitive treatment of the caldera problem[5] allows. I feel that this is so, that the 'Glencoe' mechanism is the primary mechanism involved in the majority of subsidence calderas, and that the 'Krakatoan' mechanism is in the nature of a special case, a complication of the 'Glencoe' mechanism, operating where volatiles are particularly abundant within the magma chamber at the time of subsidence. Complete gradation is believed to be possible between calderas showing only the effects associated with ring-fracture subsidence and the famous catastrophic 'Krakatoan' calderas. Menengai is supposed to exemplify a more weakly 'Krakatoan' sub-type, the explosive eruptions of pumice, which initiated the caldera, being nowhere nearly as strongly represented as in the case of Krakatoa, Santorin and Aso[6]. The outer caldera of Suswa, though larger than Menengai (43 sq. miles), shows less evidence of initiating pumice eruptions, Kilombe shows little or none at all, and the inner caldera of Suswa shows none. In spite of these dissimilarities, all these calderas are believed to have stemmed from the same primary process: the fundamental process and the secondary variations imposed on it are evisaged by me as outlined here.

(1) Main sequence of eruption from a broad shield volcano: up-doming by the agency of magmatic distension is a likely adjunct; the typical products of this main phase of eruption are lava flows, showing weathered surfaces indicative of periods of quiescence, punctuating the sequence of eruptions.

(2) The eruption, as a whole, wanes and the superstructure, probably up-arched by the main eruptive upsurge, collapses; two possible causes of this collapse may be entertained: a purely gravitational collapse and a deflation in which magma plays an active part. In the first case, the superstructure founders due to withdrawal of support. Rapid emptying of the magma chamber is usually invoked to explain this; but another factor may well be the increase in volatile content held dissolved in the residual magma, causing a decrease in viscosity. The watery end-stage magma so produced would provide a poor cushion for the superstructure, while the previous more viscous magma would sustain it. The alternative to the purely gravitational hypothesis, suggested by Oftedahl in the case of Baerum cauldron[7], invokes recession of the magma within the chamber, a cylindrical block following the magma downwards, that is being drawn down by the receding magma. Whatever the motivating force, the initiating movement downwards will open up steeply inclined fractures. These will be of essentially concentric pattern, but some complication by a limited degree of control exerted by other tectonic lines of weakness—often the intersecting fracture lines which control the position of the volcanic focus in the first place—will, perhaps, be reflected in rectilinear patterns in the caldera walls and lateral sector grabens.

(3) This initial movement downwards will set off a subsidiary reaction; the opening of the superstructure causes a sudden pressure release and the volatile-rich residual magma suffers ebullition, surging up ring-fracture conduits. If this magma is heavily charged with volatiles, pumiceous material will be erupted in vast quantities, in a series of rapid and explosive eruptions from vents arranged roughly on the trace of the ring fractures at the surface. In the case of magma with somewhat less volatile content ebullition will be weaker, and little or no ring-fracture eruption will ensue. It has been found, in the case of the Kenya calderas, that the magma composition varies only slightly throughout the eruptive sequence, and that the silica-saturated lavas, such as trachytes, are associated with evidence of more violent ebullition in this phase, having apparently more inherent volatile content, while undersaturated lavas, such as phonolites, are associated with evidence of less violent ebullition.

(4) The descent of the foundering block, which includes the superstructure and the solidified upper part of the pluton, will be stayed by violent ebullition, the gas upsurge sustaining it without further subsidence for perhaps hours or days, but, once the secondary ebullitive phase has waned, the cylinder will continue on its downwards path. This picture seems compatible with the fact that the pumice erupted in the ebullitive phase of eruption is typically truncated by the caldera fracture. In the case of certain calderas, associated with weak ebullition, the relationships observed may be different, since the pressure of ebullition is insufficient to stay the subsiding cylinder. If pumiceous products of ebullition do reach the surface, in this case they will be erupted on to the already lowered floor of the caldera. The small amount of pumice-tuff infilling the very bottom of Kilombe caldera (*op. cit.*) may well represent such a case. Sometimes only a steam-blast will reach the surface.

(5) New cycles of eruption may occur after cauldron subsidence; usually the area of activity is smaller than in the first cycle, suggesting a restricted reactivation within the original pluton. After the main upsurge of this phase of renewed eruption has waned, a second cauldron subsidence may ensue. This has occurred in the case of Suswa (*op. cit.*). However, because of the fracturing, which the superstructure will have undergone in the first episode of subsidence, it is likely that the pressure seal will never be as efficient as before, so eruptions are not likely to be so explosive in this second subsidence cycle as in the first—unless differentiation leading to more volatile-rich magma has occurred. In the case of Suswa no explosive activity heralded the formation of the second caldera.

(6) In the case of a few subsidence structures of this type, the cylinder may fail to resume its movement downwards after the ebullitive phase: this would produce an embryonic caldera, an annular pattern of vents. This pattern seems to occur within the Valles caldera, New Mexico[8], and is also seen in the internal crater progression of Clavius on the Moon.

Perhaps the most vexed question involved in the explanation of subsidence calderas is the volume deficit. Williams's calculations[5,9,10] of the volume of pumice emitted during the formation of Crater Lake, Aso, Santorin, Coseguina, and Hakone calderas led him to conclude that the volume of pumice invariably showed a deficit against the volume of the caldera formed. Magma movement at deep levels, involving dyke injection, was suggested as the agency responsible for the extra volume unaccounted for. Williams's conclusions regarding calderas[5,9,10] provide the basis of any study in this field and his unbiased assessment of the evidence has never been challenged. However, I suggest the possibility that no deep-seated migration of magma, other than injection into ring-fracture conduits on ebullition, is necessary to account for the volume deficit. Updoming, caused by magmatic distension, is known to accompany volcanic eruption (for example, ref. 11) and some relaxation and withdrawal of the magma-level without bodily migration at the end of the eruptive sequence seems acceptable. Shrinkage on crystallization, loss of volatiles, and a tendency for eruptions to continue under the influence of secondary triggering mechanisms, such as pressure release, long after the primary upsurge (whatever its nature) has waned, may all contribute to a process of simple deflation, which may, as has been suggested, be the primary agency involved in cauldron subsidence. No computations as carried out by Williams (*op. cit.*) have yet been attempted for the Kenya calderas, but observations suggest that the deficit is proportionally greater in the case of these weakly 'Krakatoan' calderas than in the catastrophic type-calderas cited by Williams.

Besides the volume deficit, there is a second anomaly apparent in the equation of subsidence calderas and cauldrons. Inwards-dipping feeder-dykes have been recognized, marginal to the calderas of Crater Lake, Oregon[9], Suswa and Menengai. In the case of Suswa the dip can be seen to steepen downwards. A study of the literature, however, reveals that ring-dykes associated with cauldrons show steep outwards dips or are vertically inclined. Rare exceptions have been attributed to later movements. If the ring feeders are the surface reflexion of ring-dykes, why this reversal of dip? Belousov[12] has shown experimentally that at the surface or near to a surface a subsiding cylinder in clay produces ring fractures exactly as seen in the Kenya calderas, inclined inwards and steepening downwards. Anderson[13,14] calculated mathematically that such a downward movement should produce steep-outward inclined fractures, which is the normal cauldron pattern. The probability would seem to be that Anderson's pattern is valid under strong containing pressure, but where the rock/air interface above the structure affects the picture, Belousov's pattern develops. In three dimensions, then, ring-dykes at deep levels should steepen and flare out into reversed cone form.

The structure envisaged seems important since it involves vertical movement producing both normal and reversed fault displacements, and suggests a higher tensional zone and a lower compression zone. Calderas are, in my view, annular analogues of the rift valleys in which predominantly vertical movements are involved (the predominant type in Kenya) and the same processes of magmatic distension, eruption, deflation and subsidence (the latter probably involving dragging downwards) seem to have produced both types of structures. If the fracture pattern suggested, combining Anderson's and Belousov's models, is the true one, then the extension of this concept to the linear volcano–tectonic rift structures may solve some of the conflicts of evidence which have caused so much controversy.

With regards to the geophysical evidence from Japan, I believe that the types distinguished as 'Krakatoan' and 'Glencoe' overlap, and that the 'Glencoe' mechanism is the primary mechanism, not simply of calderas classified as 'Glencoe' type, but of 'Krakatoan' calderas as well. I have carried out a gravimetric survey over the broad shield volcano of Menengai (report awaiting publication, Nakuru–Thomson's Falls–Lake Hannington area) and have found that a series of high values for the Bouguer anomaly are grouped around the caldera, the typical example of a 'Glencoe' type caldera on which weak 'Krakatoan' characteristics have been superimposed. This anomaly, superimposed on the low values which here characterize the Rift Valley as a whole, seems related to the ridge volcano of Menengai, and not to be direct reflexions of the caldera.

URANIUM AND THORIUM ABUNDANCES IN POSSIBLE UPPER MANTLE MATERIALS

By Dr. J. F. LOVERING and J. W. MORGAN

Department of Geophysics, Australian National University, Canberra

It is of considerable geochemical importance that accurate determinations should be made of the uranium and thorium abundances in possible upper mantle rock types since quite severe restrictions can be placed on the absolute concentrations of radioactive elements existing in the Earth's upper mantle. For example, Birch[1] has shown that the present rate of loss of heat through the Earth's crust is equal, within a factor of two, to the rate of production of heat if the Earth as a whole was composed of material with the uranium and thorium contents of the chondritic meteorites. Assuming an overall chondritic composition for the Earth, MacDonald[2] has further calculated that the material in the Earth's upper mantle above a depth of 600–700 km should have an overall uranium content of about 0·05 p.p.m. and (assuming a thorium/uranium ratio of 3·5) a thorium content of about 0·175 p.p.m.

Many workers have suggested that rocks of ultra-basic composition (for example, peridotites, garnet peridotites or dunites) are the predominant materials in the Earth's upper mantle. Modern, accurate analyses of uranium and thorium abundances in ultra-basic rocks are very few and only three different rocks have been examined so far[4,5], and even within this small sample there is not always good agreement between different analytical methods. However, what little data there are available (Table 1) suggest that the uranium and thorium abundances measured in ultra-basic rocks are about 50 times less than MacDonald has calculated for upper mantle materials.

Following an earlier suggestion by Goldschmidt, Lovering[3] has proposed that a considerable portion of the Earth's upper mantle is basic in composition but composed of pyrope-garnet and omphacitic pyroxene assemblages characteristic of eclogitic rocks. The only data available on uranium and thorium abundances in eclogites are those of Holmes and Paneth[6] published in 1936. Their results (Table 1) would suggest that the uranium and thorium abundances in the eclogitic inclusions from kimberlite pipes in South Africa are very much higher than would be consistent with their occurrence in the upper mantle. However, the methods then used for the determination of the uranium and thorium have been superseded by more precise methods (for example, neutron activation, isotope dilution, etc.), and it became obvious that a study should be made of uranium and thorium abundances in eclogites using one of these techniques. Neutron activation analysis was selected as the most appropriate technique for the determination of the relatively low levels predicted for eclogite rocks from the mantle and a method was devised to simultaneously determine uranium and thorium in the sample after neutron irradiation in the *Hifar* reactor of the Australian Atomic Energy Commission. The details of the analytical method will appear elsewhere[7]; but it can be shown that individual analyses for both uranium and thorium have relative deviations of about 2·5 per cent. Good general agreement has been found with the most reliable methods of analysis used for the determination of uranium and thorium in the Standard Granite *G*-1 and the Standard Diabase *W*-1.

Eclogitic rocks occur in two main environments on the Earth's surface. There are the pipe eclogites which occur along with ultra-basic and granulitic rocks as inclusions in kimberlitic and basic igneous pipes in various parts of the world. Some of the pipe eclogites contain

Table 1. PREVIOUS DETERMINATIONS OF URANIUM AND THORIUM IN ECLOGITIC AND ULTRA-BASIC ROCKS

		Uranium			Thorium

diamond as a primary phase and have certainly formed at depths of at least 130 km in the mantle[8]. There is strong evidence that these eclogites represent material brought directly from the upper mantle of the Earth during the emplacement of the pipes.

The other class of eclogites we have are called the crustal eclogites. These eclogites occur as lenses or discontinuous masses often (but not always) associated with peridotite and garnet peridotite masses in orogenic zones. It is possible that these eclogites have also been brought directly from the mantle during the orogenic episode which mobilized them, but the evidence for a direct mantle origin is very much less compelling than that of the pipe eclogites. In the present work samples of both crustal and pipe eclogites have been studied to give as complete a picture as possible of the uranium and thorium abundances in eclogitic rocks.

Pipe eclogites. Igneous pipes containing eclogite inclusions are known from many parts of the Earth's surface. Most of these pipes are filled with a matrix rock of kimberlitic composition in which fragments of eclogite and other rock types are included (for example, South Africa, Siberia, etc.). An eclogite (*R*269) inclusion from the Roberts Victor Mine, Orange Free State, South Africa, made available by Dr. F. A. Venter of the South African Geological Survey, has been analysed in the present work. More recently pipes filled with massive and brecciated alkali–olivine basalts and containing a suite of eclogitic and other inclusions virtually identical with those in the kimberlitic pipes have been found in eastern Australia. The Australian pipe containing the least-altered inclusions occurs near Delegate in southern New South Wales and three eclogites with slightly different mineralogical composition have been analysed from this pipe (for example, *R*117 hornblende eclogite, *R*11 eclogite, *R*394 olivine eclogite).

The eclogitic samples described so far occur in pipes which penetrate the continental crust and presumably these eclogites represent material from the continental upper mantle. It is very important to examine pipe eclogites in oceanic areas to see whether there are any significant differences between eclogites occurring in continental and oceanic upper mantle regions. Oceanic eclogites have been described as inclusions in palagonite tuff, Salt Lake Cone, Oahu, Hawaii by Winchell[9] and samples of an olivine eclogite (*R*419) from this locality were made available by Dr. G. A. Macdonald.

Crustal eclogites. Four eclogites from crustal environments have also been analysed. Eclogite *R*388 from Junction School, Healsburg Quadrangle, California, is a relatively unaltered sample of the Californian eclogites which are associated with ultra-basic rocks and glaucophane schists[10] and was made available by Dr. Iris Borg. Eclogite *R*391 (Silberbach-Hof, Fichtelgebirge) is a sample of the eclogite occurring as pods in gneisses of the German Münchberg gneiss massif[11] and was collected by Dr. R. R. Marshall. Eclogite *R*371 comes from a similar geological environment at Hof Bavarra, Germany. The olivine eclogite *R*372 occurs with ordinary eclogites and peridotites in lenses within amphibolite facies rocks of the River Tessin region of southern Switzerland. Both specimens *R*371 and *R*372 were made available by R. O. Chalmers from the collection of the Australian Museum. Other rocks described as eclogite facies rocks by Subramaniam[12] occur with meta-anorthosites in an apparently layered sequence within the Peninsular gneisses near Sittampundi, Madras. One of these rocks, classified as a 'bronzite pyropite', *R*375 has also been analysed in the present work.

The results of the analyses of these rocks are shown in Table 2, and the following conclusions can be drawn from these observations.

(1) Eclogites from the continental upper mantle have very similar uranium (range 0·04–0·07 p.p.m.) and thorium (range 0·15–0·29 p.p.m.) abundances with mean values of 0·052 p.p.m. uranium and 0·22 p.p.m. thorium. These values are at least an order of magnitude higher than those reported for ultra-basic rocks (Table 1) and something like an order of magnitude less than the average values usually quoted for basic igneous rocks[14]. The levels of uranium and thorium found in these eclogites agree very closely with the estimates made by MacDonald[1] for possible uranium and thorium abundances in upper mantle materials.

(2) The thorium/uranium ratios for the eclogites from the continental upper mantle range from 3·5 to 5·8 with a mean value of 4·2. This is very close to the value of 4·1 which Cannon *et al.*[15] have calculated for the upper mantle on the assumption that lead ore deposits have been derived from the Earth's upper mantle.

(3) The one eclogite analysed which may well represent part of the oceanic upper mantle has a uranium content identical with continental eclogites; but the thorium content is somewhat lower, so that the thorium/uranium

ratio (2·4) is considerably lower than the ratios in the continental eclogites. However, as only one oceanic eclogite has been analysed up to the present, it is not known whether there is in fact a real difference between continental and oceanic eclogites.

(4) The crustal eclogites measured had uranium contents between 0·018 p.p.m. and 0·24 p.p.m., thorium contents between 0·015 p.p.m. and 0·60 p.p.m. and thorium/uranium ratios between 0·6 and 4·8. Only one crustal eclogite (*R*371 from Hof Bavarra) had a uranium and thorium content, and a thorium/uranium ratio within the range of the continental pipe eclogites. The others show very different abundance-levels for uranium and thorium as well as very different thorium/uranium ratios from those of the pipe eclogites. However, it is not possible to conclude from the present work whether or not the majority of crustal eclogites do in fact represent portions of the upper mantle intruded into the crust during orogenic episodes. It may well be that their present uranium and thorium abundances reflect drastic modifications of normal upper mantle abundances of these elements after the particular eclogites became modified by geochemical processes within the upper crust.

(5) Marshall[11] has examined the isotopic composition of the lead extracted from the same sample of the Silberbach-Hof eclogite which was studied in our work and concluded that in order to account for the lead developed during 4·5 × 10^9 years and observed by him to-day in this sample, there should be 0·10 p.p.m. uranium and 0·41 p.p.m. thorium present. The actual amounts present in this sample (Table 2) are considerably higher than Marshall's estimates, and would suggest that the Silberbach-Hof eclogite has not remained a closed system with regard to uranium, thorium or lead over geological time.

The work is at present being extended to include granitic, amphibolitic and granulitic inclusions in the igneous pipes described previously on the assumption that these rock types probably represent samples of the deep continental crust intruded by the pipes. It is hoped that in this way a more complete picture may be built up of uranium and thorium distributions within the continental crust. Other possible upper mantle materials (such as garnet peridotites and peridotites) occurring in the pipes are also being studied.

This work is supported by a research grant from the Australian Institute of Nuclear Science and Engineering with laboratory facilities provided by the Australian Atomic Energy Commission.

LARGE RING STRUCTURES IN A SOUTH AUSTRALIAN PRECAMBRIAN VOLCANIC COMPLEX

By A. R. CRAWFORD

Geological Survey of South Australia, Adelaide

IN 1961 I noted an arcuate pattern on the outcrop of the Gawler Range porphyry 50 miles west-south-west of Port Augusta, South Australia. The Gawler Range porphyry is a loose term given to a vast (12,000 sq. miles) outcrop covering northern Eyre Peninsula. The predominance of red-weathered felspar porphyry suggested a persistently similar rock-type, comparable rocks being known in scattered outcrops 100 miles north of the railway. Lack of known mineralization within this outcrop led to neglect since its discovery by H. Y. L. Brown in 1885.

The age of the Gawler Range porphyry was uncertain. It was compared by R. Lockhart Jack[1,2] with the richly copper-bearing Moonta porphyry of Yorke Peninsula about 100 miles to the south-east. This rock intrudes Precambrian gneisses usually described as Archaean. Lockhart Jack suggested that the Gawler Range porphyry was an effusive equivalent of the Moonta porphyry.

I suggested[3] that the copper-bearing Wooltana volcanics of the northern Flinders Ranges (which are haematite-rich trachytes underlying unconformably the Sturtian glacials), the Moonta Porphyry and the Gawler Range porphyry were of common genesis and of much the same age. Other volcanics occurring in scattered outcrops between Wooltana and Port Augusta (for example, Brunnschweiler[4]) proved to be of Wooltana type. These are often either diapirically placed[5] or occur along major lineaments.

A field check of the arc noted in the Gawler Range porphyry showed that it had parallel banding and that devitrified obsidian was common. Rocks almost indistinguishable from typical Wooltana-type trachytes were found only 15 miles east of the main porphyry outcrop and recently H. W. Fander and I found similar rocks well within the main outcrop.

Eroded vents with diameters of about one mile were revealed near the arc. Numerous curved lineaments were detected, some concentric with the vents, among innumerable straight lineaments forming part of a superbly displayed rectilinear joint pattern. This pattern is ascribed to torsional stress associated with block-faulting.

An assembly of 40 to one inch to one mile mosaics, covering the whole of the main outcrop revealed very large circular structures. In the area south-west of the southern end of Lake Gairdner, and which forms the south-western part of the main outcrop, a valley with a constant width of about half a mile extends along a semicircle, having a diameter of about 35 miles. This is centred approximately on Yardea head station (that is, sheep station). Diametric to this valley (which is obviously quite distinct from innumerable straight valleys of variable width, most of which are probably widened joints) a perfect graben four miles wide extends from near Yardea for twenty miles eastward. The graben meets the semicircle on the south-westernmost inlet of Lake Gairdner, and this point is itself the centre of a complex of elliptical shape, with a larger diameter of 12 miles.

Field examination of the large semicircular structure showed no major change in rock-type across the valley, which like most valleys in the Gawler Ranges is flat-bottomed and entirely covered by alluvium, except at Paney out-station, 17 miles south-west of Yardea, after which the feature has been named. At Paney low hills between higher plateaux are formed of flow-banded porphyritic rhyolites much paler in colour than most of

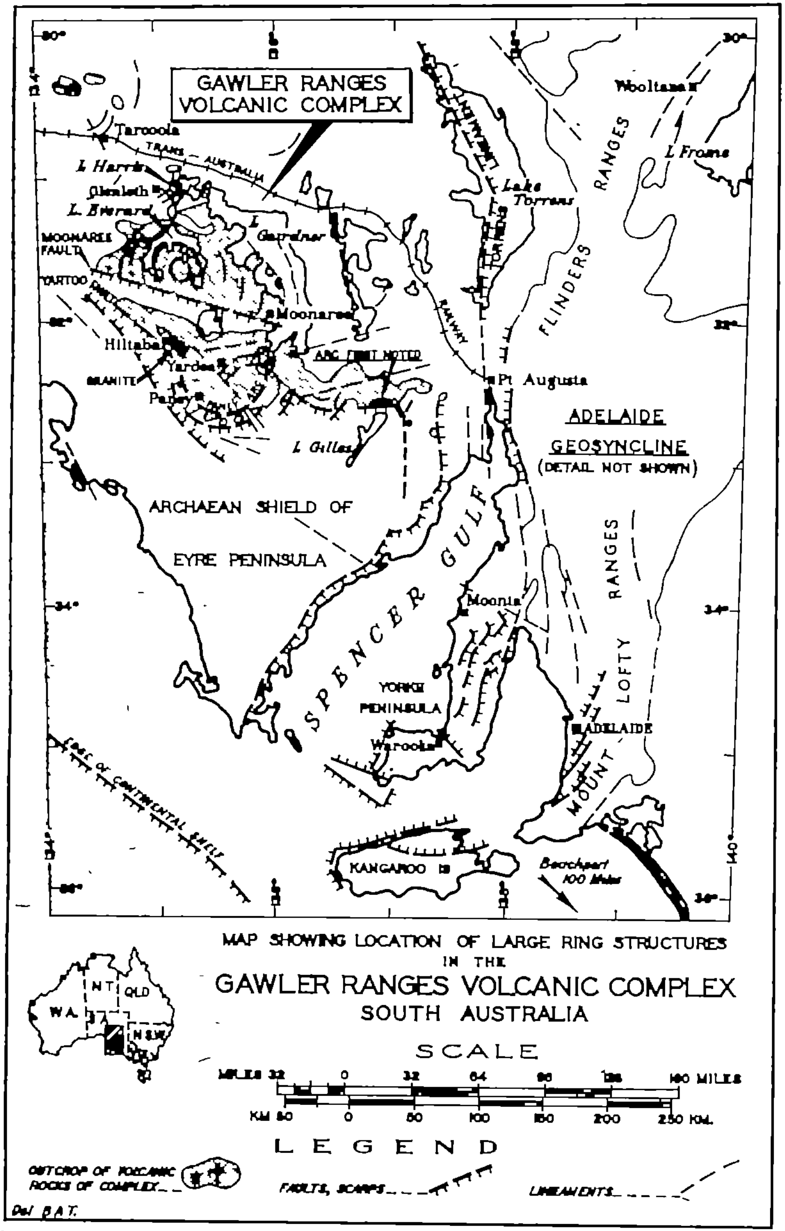

Fig. 1

the porphyry, and showing extremely tortuous, swirling textures, confined to a narrow zone about a quarter of a mile wide along the line of the semicircle. The rocks to the north and south are different, and flow-banding is not common.

A major east-north-easterly lineament extends through the Gawler Ranges for 100 miles and is almost tangential to the Arc. Along this lineament intense brecciation and chemical alteration is common and uncharacteristic rocks occur. The area within the Paney Arc appears, so far as can be determined without distant oblique air views, to have a topographic expression which is saucer-like.

Radial to the Paney Arc (and parallel to the Yartoo Fault) is a body of granite which occupies a graben-like area near Hiltaba H.S. This has a longer dimension of 15 miles, aligned west-north-west. It is a vuggy fluorite-bearing granite quite distinct in type from others in northern Eyre Peninsula. As it intrudes the porphyry to the south of it with a sharp vertical contact it may be a large radial dyke.

Numerous smaller ring structures exist, much of the southern boundary of the outcrop being formed by their intersection; some are faults which have moved in Quaternary time. Evidence for other large ring structures is accumulating. On a recent field visit during which ring patterns south of Lake Everard were checked it was clear that these are concentric with the southern shores of that lake, which had an extraordinary shape. This area too has a saucer-like topography. In so far as the westernmost limbs of the lake are also concentric, it seems almost certain that ring structures of at least 55 miles in diameter exist. The relationship of these to sympathetically curved lineaments to the east between Lake Everard and Lake Gairdner is as yet obscure, but structures of 70 miles in diameter may exist. If certain lineaments noticed in the bed of Lake Gairdner are related, this figure would have to be increased to 100 miles.

Similar arcs entirely control the west shores of Lake Harris farther north (on most maps these lakes are all inaccurately delineated) and with radial lineaments form sector-like bays. Others include andesite dykes in the adjacent Glenloth goldfield, the bedrock outcrops of which appear to form part of an annulus. In the Tarcoola district andesite dykes known to be gold-bearing are radial intrusions into sediments which are apparently down-faulted within an annulus. Copper minerals occur at Tarcoola in fine-grained variants of Gawler Range type volcanic rocks.

Numerous long, straight lineaments occur. Most are north-westerly, west-north-westerly, or east-north-easterly in direction. The most obvious is the Moonaree Fault, which extends for more than 80 miles west-north-westward from the west shore of Lake Gairdner.

Of 400 rock specimens being examined, H. W. Fander has already (personal communication) noted many welded tuffs. Age determinations by the strontium–rubidium method are in progress (by Dr. W. Compston) at the Australian National University.

The deeper implications of the large circular structures and their associated straight lineaments are still under study. One obvious comparison is with lunar structures. Jeffreys[4] states that the terrestrial structures most like lunar 'craters' are the ring-dykes first noted by Clough, Maufe and Bailey in the Tertiary volcanic complexes of the Scottish Highlands. Jeffreys noted that the largest known ring-dykes were very much smaller in diameter than the average lunar crater, but did not regard this as important. While it has not yet been possible to obtain a three-dimensional picture of the large circular structures in the Gawler Ranges Volcanic Complex, I provisionally regard the Paney Arc as having been the edge of a cauldron subsidence. The retention of original topography (as is suggested by the saucer-like topography) in rocks of such age is very unlikely but it seems possible that a rejuvenation of the major structural controls may have assisted the development of what can perhaps be described as 'palimpsest topography'.

The centre of the Paney Arc lies on the projection of a line joining the epicentres of South Australia's largest earthquakes, namely, September 19, 1902, Warooka, Yorke Peninsula, and May 10, 1897, April 8, 1948, Beachport. The centre is about as far from Warooka as Warooka is from Beachport. This line is parallel to the edge of the continental shelf off Eyre Peninsula.

The economic implications are important. The Tarcoola and Glenloth goldfields undoubtedly owe their mineralization to the volcanics. The association with copper is significant. Magmatic copper occurs in the Wooltana rocks, and gold is known. (The widespread copper mineralization of the associated Adelaide System sediments has long been regarded by me as sedimentary-exhalative in type.) 'Porphyry copper' is therefore thought to be a likely prospect in at least the north-west of the Complex. It may be significant that the only tin localities in South Australia are at and near Glenloth. Minor gold occurrences within the Complex are known. Most interesting of all is the possible connexion with the exceedingly rich hæmatite bodies of the Middleback Ranges, all of which lie in a narrow north–south belt regarded as a major structural lineament parallel to one of the most fundamental in Australia, the Torrens lineament separating the West Australian shield from the Adelaide geosyncline. Iron Monarch is the richest body and is the nearest to the porphyry outcrop. Miles *et al.*[7] believed the Gawler Range porphyry to be much younger than the ore bodies and therefore to have played no part as a magmatic source. The question should be reconsidered. It may be very significant that a large aeromagnetic anomaly lies under the northern end of Lake Gilles, due west of Iron Monarch, and at a point central to the Arc first noted; that the rocks of the Complex are invariably rich in hæmatite; and that 'Gawler Range porphyry' was recorded under the Iron Monarch orebody at about 650 ft. below surface in one drill-hole. It is also curious that a line passing through the Pancy Arc centre, and through several other centres, and parallel to the Moonaree fault also passes through the Iron Monarch orebody.

HIGH-TEMPERATURE PHASE EQUILIBRIA IN THE SYSTEM $2CaO.SiO_2 — 3CaO.P_2O_5 — CaO$

By W. GUTT

Department of Scientific and Industrial Research, Building Research Station, Garston, Watford

A DETAILED examination has been made of phase equilibria in the system $2CaO.SiO_2 - 3CaO.P_2O_5 - CaO$ characterized by liquidus temperatures in the region of 2,000° C, and by the presence of high-temperature phases which cannot be preserved by rapid cooling. This system is of importance to processes in the cement, steel and fertilizer industries, and has been much investigated, but earlier work suffered from lack of suitable experimental methods. The investigation benefited from recent elucidation of the binary system $2CaO.SiO_2 - 3CaO.P_2O_5$ (ref. 1) and of the melting behaviour of tricalcium silicate[2], and use was made of special techniques of high-temperature microscopy[1–3] capable of giving direct insight into crystal growth and crystallization sequence at temperatures up to 2,450° C.

The liquidus surface, established by these methods, which is given in Fig. 1 with abbreviated liquidus data, derives from direct distinction on the microscope stage of the phases present in the melt. This surface includes a primary crystallization field, extending to 13 per cent phosphorus pentoxide, for tricalcium silicate, the most important cementing component of Portland cement. This field was not detected by earlier investigators[4]. There are two reaction points. The first of these R_1, a ternary eutectic point between CaO, $4CaO.P_2O_5$ solid solution and $2CaO.SiO_2/3CaO.P_2O_5$ solid solution, has the composition 60·75 per cent CaO, 4·75 per cent SiO_2 and 34·5 per cent P_2O_5 (by weight) and its liquidus temperature is 1,636° C. The simultaneous presence of the three phases at the liquidus at this point was established experimentally. The tie lines shown in Fig. 1 were established at a temperature of 1,500° C.

The crystallization products compatible at 1,500° C which are shown in Fig. 1 by the compatibility triangles are based on extensive examination by X-ray and chemical analysis, and by microscopy, of selected compositions in the system after prolonged heat-treatment at 1,500°. These compositions were made from reagents at least 99·9 per cent pure. A phosphate and lime modified tricalcium silicate (C_3S'') of the approximate composition 74 per cent CaO, 25·5 per cent SiO_2, 0·5 per cent P_2O_5 (by weight) exists along the join $C_3S'' -$ PSS′ and there is solid solution between C_3S and C_3S''. The locus of the joins $C_3S - C_3S''$ and $C_3S'' -$ PSS′ was established by 'free lime' analysis of selected ternary compositions in which lime is one of the three stable crystallization products at 1,500° C. Subtraction of the 'free lime' gave the corresponding two-phase compositions on these joins. Similar treatment revealed tetracalcium phosphate altered by silica and lime (C_4P') of approximate limiting composition 60·1 per cent CaO, 3·8 per cent SiO_2, 36·1 per cent P_2O_5 (by weight) existing along the join $C_4P' -$ PSS″, there being a region of solid solution between C_4P and C_4P'. X-ray analysis of compositions in various parts of the system revealed good agreement with the phase diagram of the system $2CaO.SiO_2 - 3CaO:P_2O_5$, due to Nurse, Welch and Gutt[1], the products of sub-solidus reactions obtained at 1,500° being those predicted by the phase diagram due to these authors with the following exception. Their diagram indicates no unmixing of the continuous solid solution series of $2CaO.SiO_2$ and $3CaO.P_2O_5$ above 1,500° and would predict therefore that the joins from C_3S'' and C_4P' would be directed to PSS (75·9 per cent $2CaO.SiO_2$, 24·1 per cent $3CaO.P_2O_5$ (by weight)) the composition of maximum liquidus in the binary system and not to the compositions PSS′ (86·9 per cent $2CaO.SiO_2$, 13·1 per cent $3CaO.P_2O_5$ (by weight)) and PSS″ (62·4 per cent $2CaO.SiO_2$, 37·6 per cent $3CaO.P_2O_5$ (by weight)). The work reported here indicates that some such unmixing does occur above 1,500° into two structurally very similar solid solutions the composition of which depends on the temperature. It is suggested that PSS′ and PSS″ mark the compositions of these solid solutions at 1,500° C.

The composition PSS″ lies in the small region of the system $2CaO.SiO_2 - 3CaO.P_2O_5$ in which $\bar{\alpha}3CaO.P_2O_5 \equiv \alpha 2CaO.SiO_2$, the primary phase throughout this system[1,5], can be preserved to room temperature. The uniqueness of the PSS″ composition is supported by the sharpness of the $\bar{\alpha}3CaO.P_2O_5$ X-ray diffraction pattern that it gives. This is sharper than is given by other compositions in the small region in which $\bar{\alpha}3CaO.P_2O_5$ can thus be preserved. The same argument cannot be advanced with regard to PSS′, which inverts on cooling to the α' form of the solid solution rich in $2CaO.SiO_2$.

Evidence in support of the significance attached to the composition PSS′ was obtained by reheating at 1,650° C the compositions which led to the join $C_3S'' -$ PSS′ valid at 1,500° C, and repeating 'free lime' analysis. This

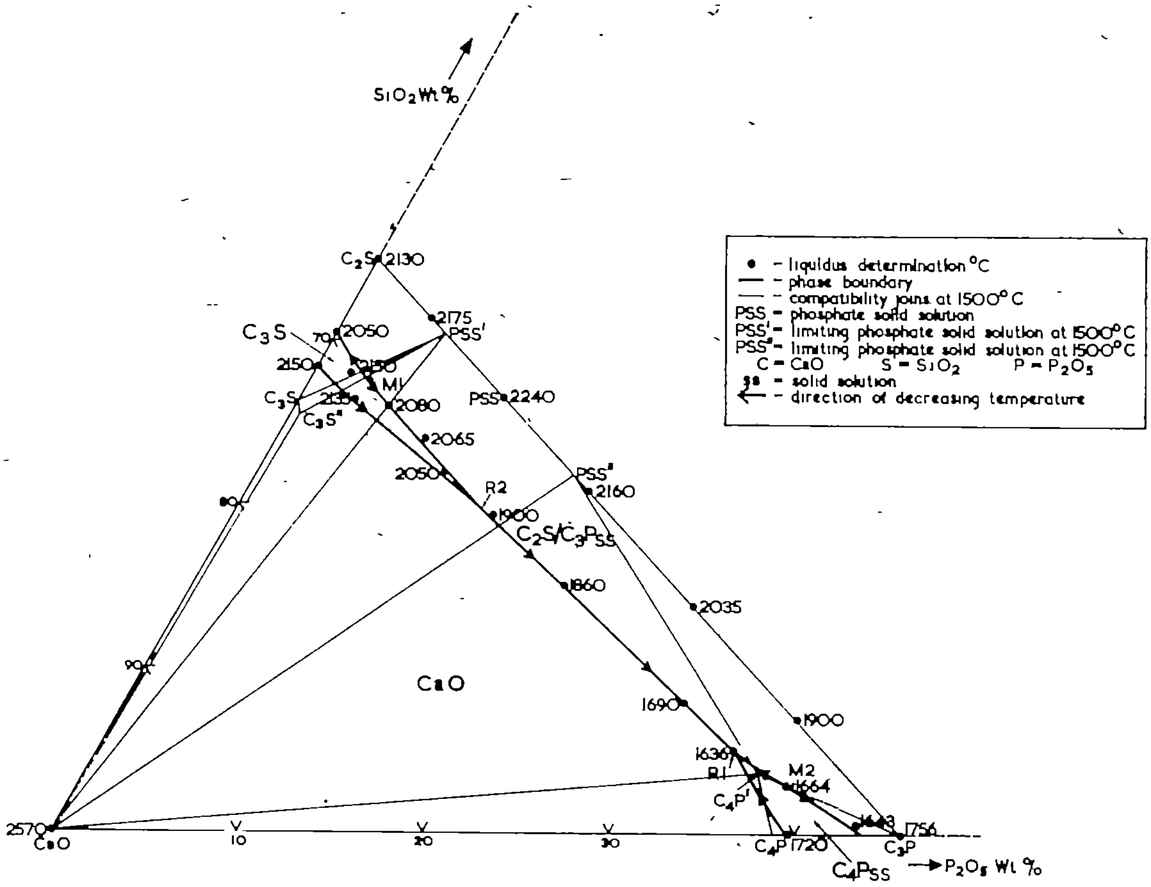

Fig. 1. Phase diagram of the system C_2S-C_3P-CaO

led to a displacement of the join from C_3S' towards a point on the $2CaO.SiO_2 - 3CaO.P_2O_5$ join richer in $3CaO.P_2O_5$ than the composition PSS′.

The liquidus maximum M_1 on the $3CaO.SiO_2$ – $2CaO.SiO_2/3CaO.P_2O_5$ solid solution boundary is in accordance with the Alkemade theorem, even assuming some displacement of PSS′ toward $3CaO.P_2O_5$ as the temperature rises.

The second reaction point R_2 between $3CaO.SiO_2$, CaO and the $2CaO.SiO_2/3CaO.P_2O_5$ solid solution occurs at the composition 67·2 per cent CaO, 19·8 per cent SiO_2, 13 per cent P_2O_5 (by weight) and its liquidus is 1,970° C. This is a 'rising reaction point'. The temperature along two of the boundaries meeting here falls towards this point and along the third the temperature rises towards it.

The liquidus maximum M_2 which may be displaced somewhat by the movement of PSS″ towards $2CaO.SiO_2$ with rising temperature on the $4CaO.P_2O_5 - 2CaO.SiO_2/3CaO.P_2O_5$ solid solution boundary is also required by the Alkemade theorem.

The incongruent melting of $3CaO.SiO_2$ in the system $CaO-SiO_2$ may occur at a temperature some 70°–80° C higher than reported by Welch and Gutt[3], but in all other respects their findings were confirmed.

MECHANISM OF THE ACTION OF NITRIC OXIDE ON PARAFFIN PYROLYSES

By PROF. R. G. W. NORRISH, F.R.S., and DR. G. L. PRATT
Department of Physical Chemistry, University of Cambridge

THE effect of nitric oxide on paraffin pyrolyses has been the subject of numerous reviews[1,2]. Briefly, the addition of nitric oxide in small amounts causes a reduction in the initial rate of decomposition of the paraffin. As the pyrolysis proceeds, however, the reaction accelerates to a maximum rate before the rate falls off towards completion. Thus, the pressure-time curve for the inhibited reaction is sigmoid in form, in contrast to the normal non-inflected curve observed for the uninhibited pyrolysis. Because of this, inhibited rates are usually defined by measurement of the initial slopes of the pressure-time curves. This procedure is sometimes complicated by the existence of either initial periods of no (or, on occasion, of negative) pressure change[3] or initial 'bursts'[4] of somewhat variable extent and duration. It is not clear whether these are genuine or are in some way due to the experimental technique, but in general they are discounted when obtaining the inhibited rate from the initial slopes. For example, spurious initial pressure decreases can be due to solution of material in stop-cock lubricant, while initial bursts can be produced by incomplete mixing (due to the practice of mixing gases in the reaction vessel) or by the presence of traces of oxygen in the reactants. It is often difficult to tell from the descriptions what precautions were taken against these difficulties. An alternative method that has been used to eliminate the effect of these 'disturbances' is to take the inhibited rate as the average rate of pressure rise between two fixed percentage pressure rises[4]. Compared with the initial rate, the subsequent stages of this self-accelerating reaction have received little attention. If increasing quantities of nitric oxide are added to the paraffin the initial rate of pyrolysis passes through a region of minimum rate in which the rate is virtually independent of the 'inhibitor' concentration, it then increases, eventually for large amounts of nitric oxide varying linearly with the concentration of inhibitor—in what is called the induced reaction. The minimum rate reached is sometimes called the residual or limiting rate. For a large number of paraffins and indeed some other substances (for example, aldehydes and ethers) it has been claimed that this limiting rate is the same under given conditions irrespective of whether nitric oxide or olefines are used to inhibit the reaction.

n-Pentane[5] is an example that is relevant to the following discussion. This equality, however, is known to be destroyed by changes of reaction temperature in the cases of 2-methyl pentane and *n*-pentane[5], by changes of the reaction vessel surface in the case of *n*-heptane[6], and by changes of reactant pressure in the case of propaldehyde[7]. The equality is only approximate; for example, in the cases of iso-butane and iso-pentane the rates differ by some 15–20 per cent, which is well outside experimental error[8]. It is well established that the olefines themselves decompose by radical mechanisms, often at appreciable rates at the temperature at which they are used as inhibitors; for example, propylene and isobutene have been used[8] to inhibit the pyrolyses of isobutane, isopentane, and *n*-pentane, at 560° C, although these olefines have been found to decompose at this temperature at rates comparable with those of the paraffin pyrolyses[9]. We think that the equality of limiting rates has not been established as exact and general. The explanation of this equality, therefore, is not a necessary requirement of any mechanism postulated for the reaction. Nevertheless, there is an overall similarity in the effects of nitric oxide and of olefines in paraffin pyrolyses that almost certainly reflects a similarity of mechanism.

Several attempts have been made to explain the observed characteristics of the effect of nitric oxide on paraffin pyrolyses in terms of detailed mechanisms[4,10–12]. In our opinion these have paid insufficient attention to the fate of the products of the reactions between the alkyl radicals and nitric oxide. The fate of these products is of the greatest significance to a clear understanding of 'inhibition'. These products are known to include oximes[13]. The pyrolyses of formaldoxime and acetaldoxime have been investigated[14,15], and found to occur very rapidly at temperatures well below those normally used for paraffin pyrolyses. The decompositions of these oximes have also been shown to be greatly accelerated by very small quantities of nitric oxide[14,15]. In the case of formaldoxime at about 400° C a violent explosion occurred when nitric oxide was added[14]. In the inhibited paraffin pyrolyses, where excess paraffin is present, this explosion might well exist incipiently. The mechanism postulated to account for the pyrolysis of acetaldoxime has been shown to give rise to the possibility of chain branching occurring in systems containing ethyl radicals and nitric oxide[15]. The reactions involved are:

$$NO + C_2H_5^{\cdot} = C_2H_5NO \rightarrow CH_3CHNOH$$

$$NO + CH_3CHNOH = (CH_3CHN)^{\cdot} + HNO_2$$

$$(CH_3CHN)^{\cdot} = CH_3^{\cdot} + HCN$$

$$HNO_2 = OH^{\cdot} + NO$$

It is suggested here that the self-accelerating nature of paraffin pyrolyses inhibited by nitric oxide can be explained by the occurrence of such a chain branching mechanism in a degenerate form. The initial 'inhibited rate', as defined by previous workers, would then correspond to a situation where the branching has not yet become significant. On this basis we suggest a simple scheme here which gives a good account of the observed characteristics of this initial rate. In the absence of more direct evidence of the fate of the products of the reactions between alkyl radicals and nitric oxide within an actual inhibited pyrolysis it is evident that any detailed mechanism proposed for these inhibited pyrolyses must to some extent be speculative. Nevertheless, the scheme which is proposed here takes account of the facts recorded above and is suggested as an alternative possibility to previous schemes: it is based on the concept of a unified mechanism for all phases of the reaction.

The three main stages in the effect of the addition of nitric oxide to decomposing paraffins, that is, inhibition, residual reaction, and induced reaction, have often been treated separately as virtually independent reactions, the overall rate of pyrolysis being obtained simply by adding together these three components in proportions appropriate to the various stages of the reaction. This approach has recently been used by Blackmore and Hinshelwood[4] to explain the three phases of the nitric oxide effect in terms of a detailed mechanism and to evaluate the relevant rate parameters involved by comparison with experimental results. Their approach postulates a true molecular decomposition which predominates in the region of maximum inhibition, and an attack by nitric oxide on the paraffin which predominates in the region of the induced reaction[1]. These authors emphasize that, since the inhibitable part of the reaction rate ($k_0 - k_\infty$), in their notation, is not very much smaller than the uninhibited reaction rate (k_0), either value may be used as the rate of the chain reaction for the purposes of the arithmetical calculation without producing very large changes in the values of the derived rate parameters. This purely numerical result does not alter the fact that the postulate of a molecular reaction is essential to their interpretation of the inhibition curve.

Thus, the fact that back extrapolation of the linear induced reaction curve to zero nitric oxide concentration gives a finite rate of pyrolysis, together with the observation that the consumption of nitric oxide relative to that of paraffin decreases markedly from near unity in the induced region to some small unknown value in the region of maximum inhibition, has been taken to indicate the existence of the true molecular component. This argument is only valid subject to the assumption of independence of the various reactions stated above. This independence is *a priori* very unlikely, particularly so for radical chain reactions. Further, the continuity observed in certain product ratios throughout the inhibition by propylene militates against separate concurrent reactions in this case[16]. A single scheme embracing the whole range of reaction would be more satisfactory, but has been discounted by Blackmore and Hinshelwood[4] on the grounds of the varying kinetics observed in the different regions. Such a single scheme which satisfies these kinetics, however, is presented here.

In the simplified scheme for a paraffin pyrolysis written below, the symbols have the following significance: P = paraffin, R_L = 'large' radical (for example, C_2H_5, C_3H_7, etc.), R_S = 'small' radical (for example, CH_3, H), M = inactive product, Ol = olefinic product.

$$P = R_L + R_S \tag{1}$$

$$R_S + P = M + R_L \tag{2}$$

$$R_L = Ol + R_S \tag{3}$$

$$R_L = \text{end-products} \tag{4}$$

The termination step (4) is written as first order for simplicity; its kinetics are not important when the extent of inhibition is large. If we represent the oximes isomeric with RNO by *Ox*, then in the presence of nitric oxide the following reactions occur:

$$R_L + \mathrm{NO} = \mathrm{RNO} = Ox \qquad (5)$$

The oximes formed in this manner will undergo both a rapid pyrolysis and a nitric oxide catalysed pyrolysis. As outlined above this latter reaction cannot lead to significant branching in the initial stages of the reaction, so we may write:

$$Ox + \mathrm{NO} = R_s + \text{products} \qquad (6).$$

For example (6) could be:

$$\mathrm{CH_3CHNOH + NO = CH_3^{\cdot} + HNO_2 + HCN}$$

If, for simplicity, we assume that the uncatalysed decomposition of *Ox* yields only inactive products we may include:

$$Ox = \text{products} \qquad (7)$$

Should this decomposition, in fact, involve radicals which sensitize the paraffin pyrolysis[16], then it may be shown that this will not influence the overall kinetics of the reaction, but will lead only to some alteration in the coefficients of [NO] in the rate expression given below. The reactions (1)–(7) written above constitute a mechanism for the pyrolysis of a paraffin in the presence of nitric oxide which has been much simplified by the grouping together of many reactions and the exclusion of many others. In spite of this it may still be expected to represent the basic pattern of the true mechanism.

Applying a steady-state treatment to R_L, R_s, and *Ox* (*Ox* is very unstable at the temperatures normally used, for example, at 800° K, $(k_7/k_1) > 10^5$ for $R_L = \mathrm{C_2H_5^{\cdot}}$) leads to the following result for the rate of paraffin destruction in the 'steady' initial state:

$$\frac{1}{[P]}\,\frac{\mathrm{d}[P]}{\mathrm{d}t} = 2k_1\left\{1 + \frac{(k_2k_7/k_5k_6) + (k_3/k_5)[\mathrm{NO}] + [\mathrm{NO}]^2}{(k_4k_7/k_5k_6) + [(k_7/k_6) + (k_4/k_5)][\mathrm{NO}]}\right\}$$

This result predicts the observed shape of the 'inhibition curve', that is, a very rapid drop in rate for small additions of NO, to a minimum rate which is not zero, followed at larger concentrations of NO by an 'induced' reaction which is first order in both [NO] and [*P*] and which does not extrapolate back to zero but to a finite rate, equal to $2k_1\{1 + (k_3/k_5)/[(k_7/k_6) + (k_4/k_5)]\}$, at zero [NO]. This extrapolated first order rate constant being a complex function of several rate parameters would not be expected to show the normal properties of a single unimolecular constant. The unusual variations of order and activation energy with pressure observed by Hinshelwood *et al.* for this extrapolated rate constant which conflict with the predictions of present theories for true molecular reactions would be explainable on this basis.

As an example, we may take the case of 100 mm Hg of *n*-pentane at 540° C studied by Blackmore and Hinshelwood[4]. The curves in Fig. 1 are calculated from the foregoing expression using $k_1 = 1{\cdot}78 \times 10^{-5}(s^{-1})$, $k_2/k_4 = 17{\cdot}6$, $k_3/k_5 = 2{\cdot}18 \times 10^{-6}$ (mole c.c.$^{-1}$), $k_6/k_7 = 0{\cdot}587 \times 10^7$ (c.c. mole^{-1}). This value of k_1 compares favourably with that evaluated for *n*-butane by several workers, for example, Trotman-Dickenson[17] gives $10^{17} \exp(-80{,}000/RT) = 3 \times 10^{-5}(s^{-1})$ at 540° C, while Quinn[18] gives $10^{17{\cdot}6} \exp(-86{,}300/RT)$, that is, $0{\cdot}4 \times 10^{-5}$ (s^{-1}) at 540° C. The ratio k_2/k_4 is the uninhibited chain length and the value of 17·6 is therefore well within the accepted range. If k_3 is taken to be $10^{11} \exp(-23{,}000/RT)$ as given by Bywater and Steacie[19] for the corresponding decomposition of the butyl radical, this is 6×10^4 (s^{-1}) at 540° C. This, together with the above value for k_3/k_5, gives $k_5 = 3 \times 10^{10}$ (c.c. mole$^{-1}s^{-1}$). This value is only slightly less than that measured for $\mathrm{CH_3^{\cdot}}$ + NO, that is, 10^{11} (c.c. mole$^{-1}s^{-1}$), and this is not unreasonable in view of the larger radicals involved in reaction (5). Further, if k_5 is in fact slightly greater than that for butyl radicals this will increase the estimate of k_3. The value of k_6/k_7 for the case $R_L = \mathrm{C_2H_5^{\cdot}}$ may be independently estimated from the known acceleration of acetaldoxime pyrolysis by NO at 500° K. This gives $k_6/k_7 = 4 \times 10^7$ (c.c. mole^{-1}) at 500° K. The slightly lower value taken here could correspond to E_7, being greater than E_6 by some 5 or 6 kcal or to larger radicals being involved. Hence it may be concluded that the rate parameters assumed here are all in quite reasonable agreement with established values.

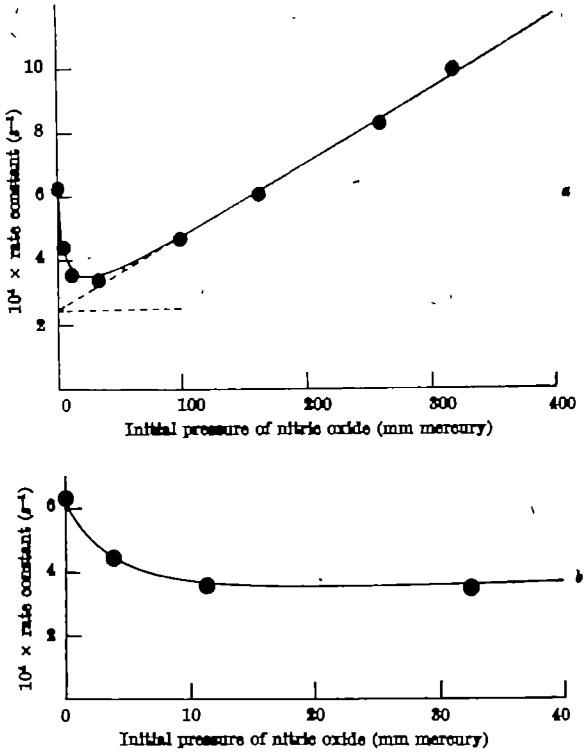

Fig. 1. Comparison of a calculated inhibition curve with the experimental points of Blackmore and Hinshelwood (ref. 4) for 100 mm mercury of *n*-pentane at 540° C

The experimental points in Figs. 1*a* and *b* were obtained from the graph of Blackmore and Hinshelwood[4]. Fig. 1*b* shows the first part of Fig. 1*a* on a larger scale to illustrate the similarity of the calculated curve to the 'flat' minimum normally associated with inhibition curves. The experimental points on the latter are rather rough, being taken from the larger graph. Unfortunately, the curve cannot be compared with the inhibition data obtained in this region by Stubbs and Hinshelwood[8] for 100 mm mercury of *n*-pentane at 530° C since their results as presented are not comparable with those of Blackmore and Hinshelwood to which the curve was fitted. In the former work the rate was reduced by a factor of seven at the minimum, while in the latter investigation only a factor of two reduction was obtained. This divergence between results as variously recorded strengthens the case against the use of inhibition curves in the manner adopted by these latter workers. The close similarity between these calculated curves and those observed experimentally is very striking. Clearly, by suitable choice of the rate parameters the curves could be made to fit the data for any other particular case, and furthermore the values so obtained would be well within the accepted limits for these rate constants.

As further examples, Table 1 gives values of the rate parameters obtained by fitting the foregoing expression to the graphs of Blackmore and Hinshelwood[4] for the three isomeric pentanes at 540° C. The values are somewhat approximate, owing to the error involved in matching the curve to a small scale graph.

The trends in both k_1 and k_2/k_4 with increasing degree of branching of the paraffin chain are the same as those deduced by Blackmore and Hinshelwood[4] and are therefore capable of the same explanations. The trends in k_3/k_5

Table 1. PARAMETERS FOR THE THREE PENTANES AT 540° C

	n-Pentane	Isopentane	Neopentane
k_1 (s^{-1})	$1·8 \times 10^{-3}$	$2·4 \times 10^{-3}$	$3·0 \times 10^{-3}$
k_3/k_4	17·6	12·6	1·8
k_3/k_6 (mole c.c.$^{-1}$)	$2·2 \times 10^{-6}$	$1·8 \times 10^{-6}$	$0·4 \times 10^{-6}$
k_6/k_7 (c.c. mole^{-1})	$5·4 \times 10^{6}$	$8·4 \times 10^{6}$	$0·5 \times 10^{6}$

and k_6/k_7 are also regular. Taking the quotient of the second and third lines gives k_6/k_4 to vary in the ratios 8 to 7 to 4·5 from normal through iso- to neo-pentane. This, therefore, shows a regular trend of decreasing rates of addition of nitric oxide to the more branched (and therefore sterically hindered) radicals. This is in contrast to the results of Blackmore and Hinshelwood for k_6/k_4 which do not show a regular variation, though they agree in that this ratio is smaller for neopentane than for normal or isopentane. The marked decrease in k_6/k_7 for neo-pentane seen in Table 1 is perhaps understandable, as in this case some of the nitroso compounds present are unable to isomerize to the oxime without undergoing structural isomerization of the carbon skeleton. Since this process is likely to be slow these tertiary nitroso compounds may suffer alternative fates. This would increase the rate of termination of chains by NO compared with propagation, and hence decrease the effective value of k_6/k_7.

The present approach, therefore, agrees with that of Blackmore and Hinshelwood in producing regular trends in rate parameters. Moreover, it has been shown to lead to more reasonable absolute values, particularly for k_6. The value of k_1 for *n*-pentane given above ($1·78 \times 10^{-3}$ s^{-1}) agrees very well with that of Blackmore and Hinshelwood, that is, $1·7 \times 10^{-3}$ s^{-1}, but the discrepancy increases going through iso- to neo-pentane. The value given by these workers for this latter case, that is, $> 1·9 \times 10^{-4}$ s^{-1}, cannot easily be accepted, however, since it exceeds their experimentally observed value for the overall rate of pyrolysis in the absence of NO.

The ratio of the rates of consumption of paraffin and of nitric oxide is given by this scheme as:

$$\frac{\dfrac{d[\mathrm{NO}]}{dt}}{\dfrac{d[P]}{dt}} = \frac{\left(\dfrac{k_7}{k_6}\right)[\mathrm{NO}] + [\mathrm{NO}]^2}{\left(\dfrac{k_7}{k_6}\right)\left(\dfrac{k_4}{k_5} + \dfrac{k_3}{k_5}\right) + \left(\dfrac{k_7}{k_6} + \dfrac{k_4}{k_5} + \dfrac{k_3}{k_5}\right)[\mathrm{NO}] + [\mathrm{NO}]^2}$$

Hence, as observed experimentally, this ratio tends to unity at large concentrations of NO. During the inhibition, however, at small concentrations of NO this result predicts a very small consumption of NO compared with paraffin. For example, taking the values for *n*-pentane in Table 1, we obtain for this ratio where the induced reaction is negligible or corrected for:

$$\frac{d[\mathrm{NO}]/dt}{d[P]/dt} \simeq \frac{(k_6/k_3)[\mathrm{NO}]}{1 + (k_6/k_7)[\mathrm{NO}]} = 6 \times 10^{-2} \text{ for NO at 25 mm mercury pressure}$$

Thus a single simple radical chain scheme can be constructed using only known reactions to explain the whole range of the inhibition curves from true inhibition, through a 'flat' minimum rate region, to a linear 'induced reaction' region. It is therefore not necessary to consider these regions as separate and completely independent reactions, and the back extrapolation of the induced reaction to a finite intercept at zero nitric oxide concentration cannot be regarded as evidence for a true molecular component in the reaction. Nor can the low rate of consumption of nitric oxide in the region of minimum rate be so regarded.

Doubtless, numerous other similar schemes can be devised which will produce a rate expression similar to that derived here. For example, the following likely reactions could be added to those used here:

$$R_L + \mathrm{NO} = \mathrm{Ol} + \mathrm{HNO}$$
$$\mathrm{HNO} = \mathrm{NO} + \mathrm{H}$$

This is equivalent to a catalysis of reaction (3) by NO, so that k_3 is replaced by (k_3 + k'_3[NO]). This leaves the form of the rate expression unchanged, only the coefficients of [NO] and $[\mathrm{NO}]^2$ in the numerator being altered. Again, suitable choice of the rate parameters could reproduce the experimental curves.

The mechanism proposed here may be an oversimplification of what actually occurs in the reaction, but it serves to show the importance of a clear knowledge of the role of oximes, their decomposition and reaction with nitric oxide, in these inhibitions.

ANTIGENICITY OF SYNTHETIC POLYPEPTIDES WITH KNOWN AMINO-ACID SEQUENCE

By PROF. A. E. AXELROD, ANTHONY C. TRAKATELLIS and PROF. KLAUS HOFMANN
Biochemistry Department, School of Medicine, University of Pittsburgh

ELUCIDATION of the precise structural requirements for antigenicity constitutes a critical problem of modern immunochemistry. Despite concerted efforts in this area, many aspects of this intriguing question still remain unsolved. A rather recent approach to this problem involves use of a variety of synthetic polyamino-acids of the following types: (1) linear polymers of single amino-acids; (2) linear copolymers of two or more amino-acids in varying ratios; (3) branched multi-chain copolymers; (4) polypeptidyl proteins in which new polypeptides and possibly some unsubstituted amino-acids have been coupled to reactive amino groups of a native protein. Utilization of these model compounds has yielded information on the influence of various structural features on antigenicity and the antigen–antibody interaction[1]. But lack of precise knowledge of the sequential

arrangement of the amino-acid residues in these polymers, as well as their heterogeneity, restricts their usefulness for this purpose. In an effort to circumvent these difficulties, we undertook an investigation of the possible antigenicity of synthetic homogeneous polypeptides possessing a defined sequential arrangement of their amino-acid residues. Polypeptides satisfying these criteria have become available to us as an outgrowth of extensive studies in this laboratory on the chemistry of peptides related to the amino-acid sequence of the corticotropins[2]. Unexpectedly, it was found that certain of these peptides were markedly antigenic.

Male albino guinea pigs of the Hartley strain (350–450 g) were housed in individual cages with wide-mesh screen bottoms and fed a laboratory chow diet (Purina guinea pig chow, Ralston Purina Co., St. Louis). Structures and ACTH activities of synthetic peptides utilized in these investigations are shown in Table 1. Solutions of peptides in isotonic saline were emulsified with an equal volume of Freund's complete adjuvant and 0·1 ml. of the resulting emulsion injected into each of the four foot pads. Unless indicated otherwise, a total of 200 μg of the peptide administered in this fashion constituted the primary immunizing injection. In a few instances, emulsification was accomplished with an incomplete Freund's adjuvant lacking *Mycobacteria*. For booster injections, the peptides were always emulsified in complete Freund's adjuvant and administered intraperitoneally. Skin reactions were observed following intradermal injection of 10 μg of the peptide in 0·1 ml. of isotonic saline. Area and intensity of erythema, together with changes in skin thickness, served as criteria for estimation of degree of reaction[7]. Reactions of skin were characteristic of the delayed hypersensitivity type with no response at 4 h and maximum reaction at 24 h following challenge. No skin reactivity to any of the peptides was observed in non-immunized animals. Reactions at 24 h were classified as negative when the diameter of erythema was < 5 mm and change in skin thickness < 0·25 mm; strongly positive (+++) reactions exhibited a diameter of erythema > 20 mm and a change in skin thickness > 1·0 mm. Good correlation existed between degree of erythema and skin thickness changes. Anaphylactic reactivity was determined by injecting 2 mg of the peptide in 0·2–0·4 ml. of isotonic saline via a vein of the penis or intracardially. Serum agglutinins were estimated by the hæmagglutination procedure of Boyden[8] and Stavitsky[9]. For sensitization of the sheep erythrocytes, 5 ml. of a 2·5 per cent suspension of tanned erythrocytes in isotonic saline were added to 20 ml. of buffered saline (pH 6·4) and the resulting suspension coated with 5 mg of the respective peptide dissolved in 5 ml. of isotonic saline. Sensitivity of splenic mononuclear cells was determined with a previously described procedure[7]. In this method, migration of splenic cells from a sensitized animal is inhibited *in vitro* through contact with the respective allergen. Similar cells from non-immunized animals remain unaffected by this treatment.

Studies of the antigenicity of various peptides as measured by production of (*a*) skin hypersensitivity (Table 2), (*b*) anaphylactic sensitivity (Table 3), (*c*) circulating agglutinins (Table 4), and (*d*) *in vitro* sensitivity of splenic cells revealed the following salient features. Peptide *F*-23 did not effect an immunological response in any of the foregoing systems. Furthermore, this peptide exhibited no cross-reactivity with *P*-23, *P*-20, or *P*-16 in the skin hypersensitivity or *in vitro* sensitivity tests. In contrast, both *P*-23 and *P*-20 were antigenic. Peptide *P*-23 elicited an immunological response in all four systems while the antigenicity of *P*-20 was evidenced in the two reactions studied, that is, skin hypersensitivity and *in vitro* sensitivity of splenic cells. In these two systems, *P*-23 and *P*-20 were capable of cross-reacting with each other. Animals immunized with either *P*-23 or *P*-20 cross reacted with *P*-16 and *P*-13 in the skin tests. Peptide *P*-16 was less potent than either *P*-23 or *P*-20 in its ability to induce delayed hypersensitivity reactions of skin and was incapable of sensitizing splenic cells.

In this study we have utilized a series of peptides corresponding to N-terminal sequences of ACTH. With the exception of *F*-23, which possesses essentially the full biological activity of ACTH, these peptides are practically devoid of adrenocorticotropic activity (Table 1). It is of

considerable interest that protection of the *N*-terminus by an acetyl group and formylation of the lysine ε-amino groups eliminates almost completely the ACTH activity. The adrenocorticotropic potency of the unprotected eicosapeptide is essentially the same as that of the unprotected tricosapeptide (*F*-23) (ref. 5). In contrast to their protected analogues *P*-16 and *P*-13, the corresponding unprotected *N*-terminal hexadecapeptide and tridecapeptide also possess ACTH activity albeit of a low order of magnitude (< 0·1 U/mg). The observation that antigenic potencies of *P*-23 and *P*-20 exceed that of *P*-16 emphasizes the correlation between antigenicity of the protected peptides and adrenocorticotropic activities of their unprotected analogues and suggests that the antigenic and corticotropic determinants may be related chemically.

The demonstration that the synthetic tricosapeptide (*F*-23) of established structure[4] which corresponds to the arrangement of the *N*-terminal 23 amino-acid residues of pig corticotropin possesses essentially the full adrenocorticotropic potency of the natural hormone strongly supports the proposed structure for this section of the molecule. Since this portion of ACTH has been shown to be identical in all species investigated, it is likely the *N*-terminal sequence of guinea pig ACTH. The non-antigenicity of *F*-23 suggests that the antigenic determinants of the ACTH molecule reside in this *N*-terminal sequence. Failure of *F*-23 to serve as an antigen could also be interpreted on the basis that this biologically active compound becomes bound to naturally occurring receptor molecules and thus fails to reach sites of antibody synthesis. On the other hand, the non-attached, biologically inactive protected peptides would be free to exert antigenic activity.

Impressive progress in peptide synthesis and purification has provided almost unlimited possibilities for structural variations and has served to identify structural features essential for a variety of biological functions. Our demonstration of the antigenicity of relatively low molecular weight synthetic peptides has provided a new tool for studies on relation of structure to antigenicity and the antigen–antibody interaction.

This investigation was supported by grants from the U.S. Public Health Service (*A*–727 and *AM*–01128–07). We thank Dr. Warren R. Stinebring for help in the *in vitro* sensitivity tests.

OBSERVATIONS BY BIOCHEMICAL ANALYSIS AND AUTORADIOGRAPHY ON LABELLED DEOXYRIBONUCLEIC ACID IN THE NORMAL AND REGENERATING LIVER OF MICE

By DR. FINN DEVIK*

Statens Radiologisk-fysiske Laboratorium, Montebello, Oslo

AND

MISS KAREN HALVORSEN

Institutt for Atomenergi, Lillestrøm, Norway

IT is generally assumed that the deoxyribonucleic acid (DNA) of the cell nucleus is a very stable substance. Much evidence has been collected which indicates that once DNA has been synthesized, it remains in the cell until the cell dies. This is a basic assumption for much of the fundamental work which is being done by means of labelled precursors of DNA, and subsequent identification of labelled DNA in autoradiographs[1,2]. In recent years it has been suggested that DNA also has metabolic characteristics[3], but this view has been contested. The present communication reports data which indicate that DNA, as characterized by conventional biochemical methods, displays different physico-chemical properties under different physiological conditions.

The observations which led to the present series of experiments were made during a series of experiments designed to study the possible biological effect of a radioactive label incorporated into DNA in long-term experiments with mice. Tritiated thymidine was used as labelled precursor. Thymidine is considered as a precursor specific of DNA, and the activity demonstrated in a tissue after administration of labelled thymidine as an indication of the amount of labelled DNA present.

We recorded the total activity in several organs of mice at varying times after injection of tritiated thymidine. In normal mice we observed a decrease in the total activity

Results of analyses for radioactivity, and per cent labelled cells. The single figure in italics in parentheses of columns II, VII and VIII indicates the number of mice. The figures in parentheses of columns III and IV indicate the number of analyses performed. Owing to the small numbers the variations have not been characterized by statistical symbols, but the highest and the lowest values recorded have been given in parentheses under the mean figures of columns II and VII

of the liver very similar to the results published by Gerber *et al.*[4], who measured the specific activity in the DNA isolated from the liver of normal rats after injection of tritiated thymidine. From their data it is seen that the activity of the DNA of the liver was reduced to one-half in about 15 days. On the other hand, Hecht and Potter[5], and Fresco and Bendich[6] found that the specific activity of the DNA in the liver remained essentially constant for a period of up to 4 months, after injection of orotic acid-6-^{14}C, adenine-1,3-^{15}N, and glycine-2-^{14}C, respectively. These latter experiments were, however, performed with rats that had been subjected to partial hepatectomy shortly before being injected with the labelling substance.

An experiment was therefore set up to compare the activity of labelled DNA in the liver of partially hepatectomized and normal mice, following injection of tritiated thymidine. The activities in the whole organ, and in the isolated DNA fraction, were determined quantitatively, and supplemented by the study of autoradiographs of sections of the organs.

Forty-four male mice of the *WL* Oslo strain were used (85–88 days old, and weighing about 25 g). By means of a thermocauter, about 25 per cent of the liver was removed in 22 mice, under ether anaesthesia. After 42–44 h 20 μc. tritium-labelled thymidine in 0·25 ml. sterile saline was injected intraperitoneally (Radiochemical Centre, Amersham, Great Britain, specific activity 4·5 c./m.mole). The same amount was simultaneously injected, in an identical manner, from the same solution, into each of 22 normal mice from the same batch, which were to serve as controls. The mice were killed by neck luxation 1 day, 8 days, 30 days, and 116 days after injection. The liver was removed and rapidly frozen, and kept below − 20° C until the radiochemical analyses were performed. For these analyses the livers from each sampling were pooled. A small part of the livers was not frozen, but fixed in 4 per cent neutralized formalin solution for autoradiography. Material from the kidneys was secured in the same way, to serve as a cross-check between the two groups.

The pooled liver samples were homogenized in a Potter–Elvehjem homogenizer. Aliquots of the 10 per cent homogenates were subjected to direct assay of the radioactivity. The remaining parts of the homogenates were used for separation of the nucleic acids. The nucleic acids were isolated as described by Schneider and Potter[7], and DNA was separated from ribonucleic acid (RNA) by alkaline digestion[8].

The concentration of DNA was determined quantitatively by the specific colorimetric method of Ceriotti[9]. Tritium was measured by dissolution of the sample in hyamine and liquid scintillation counting[8]. Radioactivity was determined in DNA, RNA, and in the acid-soluble fraction. No tritium was detected in the separated RNA. The acid-soluble fractions contained small amounts of tritium.

For autoradiography the fixed material was dehydrated by means of ethanol, transferred through xylene, embedded in paraffin wax, and sections were cut at 6μ thickness. The sections were deparaffinized in xylene, carried through ethanol to water, and mounted with Kodak *AR* 10 stripping film[10]. They were exposed for 30 days at + 4° C before being developed (the 8 day series were exposed for 60 days).

The solutions of tritiated thymidine were stored for four months at about − 22° C, when they were subjected to paper chromatography. 91–94 per cent of the activity were recovered in the thymidine fraction, confirming the purity of the preparation.

The results of the analyses have been corrected arbitrarily to a body-weight of the mice of 20 g, by multiplying the activities by a factor = body-wt. (g)/20 g assuming that changes in organ weight were proportional to those in body-weight. No corrections were made for the autoradiographic counts. The amount of liver tissue removed was not corrected for, since the weight of the liver one day after injection differed less than one standard deviation from the arithmetic mean of all the controls (4·5 ± 0·45 per cent of body-weight). The removal of about 25 per cent of the liver tissue had at this time, about 3 days post operation, been compensated for by an increase in the liver weight to near normal values. The results are given in Tables 1 and 2.

Table 2

	Total activity ratio hepatectomy/control		Labelling index ratio hepatectomy/control	
	Liver	Kidney	Liver	Kidney
1 day	1·6	0·88	10	2·1
8 days	1·5	0·93	18	1·4
30 days	2·6	0·88	9	0·5
116 days	4·7	1·09	19	1·6

The figures of the total activity and the numbers of labelled cells in the partially hepatectomized mice have been divided by the corresponding figures of the control mice, to show the relation between the results of the test and the control series.

Six main points may be noted from the Tables.

(1) The total activity of the liver on the first day was only 1·6 times higher in the partially hepatectomized mice than in the control mice. In a previous experiment we found that the activity in the liver of normal mice killed 2–3 h after injection was 1·6 times higher than the activity in the livers sampled 24 h after injection. For the sake of argument we therefore consider it safe to state that the initial incorporation of radioactivity was similar in the two groups.

The total activity of the partially hepatectomized group remained at nearly the same level during the four months of the experiments, whereas that of the control group underwent a substantial decrease, in accordance with the results obtained by the authors quoted here[4–6].

(2) In the partially hepatectomized group the activity was almost completely accounted for by the DNA fraction. Although the main part of the activity was also

found in the DNA fraction in the control group, the deficit was consistently bigger.

(3) The activity in the acid-soluble fraction was low in the partially hepatectomized group, but consistently higher in the control group.

(4) The labelling index of the liver in the partially hepatectomized group was one order of magnitude above that of the control group; the number of silver grains in the film above the labelled nuclei was also distinctly higher in the partially hepatectomized group than in the control group. It should be noted that the autoradiographs of the two groups were exposed and processed together.

(5) From published data a substantial increase in the rate of DNA synthesis was to be expected in the regenerating liver at the time of injection, as is apparently borne out by comparing the autoradiographs. The high index of labelled nuclei observed in the partially hepatectomized series is in agreement with results published by Lesher *et al.*[11]. It is therefore striking that the incorporation of activity in the normal liver was of the same magnitude as that of the regenerating liver.

(6) From Table 1 it is seen that the total activity of the kidneys was not significantly different in the partially hepatectomized group and the control group.

From Table 2 it is seen that the labelling index observed in the kidneys was also very similar in the two groups, taking into account the considerable variability of the results to be expected from quantitative autoradiographic analysis with tritium used as a label.

Point 6 is taken as supporting evidence that the differences observed in the liver in the two series by two different techniques are real.

The gradual decrease in activity of DNA of the control series, and the low degree of labelling of the same observed in relation to the activity recorded, may be explained in several different ways: (*a*) by cell turn-over; (*b*) by metabolic DNA turn-over; (*c*) by heterogeneity of DNA; (*d*) by labelled DNA precursors.

(*a*) Assuming that the label is located only in DNA, a higher turn-over of cells in the normal liver than in the regenerating liver might account for the decrease in the control series. This in itself does not seem very likely. Also, it does not fit well with the fact that mitoses are so rarely seen in the liver and that it is scarcely compatible with a cell turn-over of the order of one month or less[4], though this possibility cannot be completely discarded. It does not explain the autoradiographic results.

(*b*) A metabolic turn-over of DNA in the control series is conceivable, though a difference in DNA turn-over would have to be assumed in cells of a normal and a regenerating liver. The reduced labelling in the control series is not explained in this way.

(*c*) The differences observed may be due to different physico-chemical properties of DNA synthesized in normal and in regenerating liver and it may be an expression of heterogeneity of DNA[12]. This could account for the different percentage of activity found in the DNA fraction of the two series (2), and the differences in the acid-soluble fractions (3). It could also account for the different degree of labelling observed in the autoradiographs, but not so easily for the decreasing activity of the control series.

(*d*) The same arguments as under (*c*) apply to labelling of DNA precursors. These would also seem more likely than DNA having a metabolic turn-over.

Taking into account the observation mentioned under point (6), we favour the opinion that the substance in the DNA fraction of the analysis is heterogeneous and may perhaps include DNA precursors besides what may be termed true, genetically stable DNA. It also seems likely that the labelled thymidine is utilized differently in normal and in regenerating liver.

The results described have implications for the theoretical background behind the use of labelled thymidine as an indicator of DNA synthesis. Assuming that DNA is metabolic stable, thymidine cannot be regarded as a precursor for the stable DNA only: and vice versa, if one assumes that thymidine is either promptly incorporated into DNA only or degraded, it is scarcely reconcilable with DNA as a metabolic stable substance.

Most experience with labelled thymidine relates, however, to rapidly dividing cells, such as in bone marrow, intestinal epithelium, and tissue culture, as also is the case in the regenerating liver. It is possible that thymidine under such conditions is very specific as a DNA precursor, and that it is utilized only or mainly for stable DNA, as seems likely from the available experimental evidence.

But the results presented in this communication indicate that the substance(s) into which the labelled thymidine is incorporated may display different physico-chemical properties under different physiological conditions, and that the label is not always to be found in the metabolic stable DNA.

We thank Prof. L. Kreyberg, Institutt for Generell og Eksperimentell Patologi, Rikshospitalet, Oslo, for providing the experimental animals and placing facilities at our disposal, Mr. Per Fritzson, Norsk Hydros Institutt for Kreftforskning, Montebello, for advice, and Miss Nancy Ljøstad for assistance.

MYELOCYTE-METAMYELOCYTE TRANSITION IN THE BONE MARROW OF THE DOG

By MARY A. MALONEY, CHARLOTTE L. WEBER and Dr. HARVEY M. PATT

Division of Biological and Medical Research, Argonne National Laboratory, Argonne, Illinois

THE granulocytes constitute a steady-state renewal system, cells being born in the bone marrow and lost in the periphery. Although the general chronology of granulocyte development is known[1,2], the dimension of time alone reveals only a part of the over-all picture. It is necessary to determine the flow of cells to understand the population relationships. This article is concerned with the flow of cells from the proliferating to the non-proliferating compartments in the bone marrow of the dog as revealed by autoradiographic analysis after labelling with tritiated thymidine. There are several transitions during granulocytopoiesis, that between myelocyte and metamyelocyte being particularly important, since the former is the last of the dividing granulocytes and the latter the first of the non-dividing granulocytes in the developmental sequence.

Two eight-month-old beagles were injected intravenously with tritiated thymidine (0·3 mc./kg body-weight; specific activity 360 mc./m.mole). The experimental procedures of bone marrow sampling and autoradiography have been described elsewhere[3]. It is generally agreed that tritiated thymidine is incorporated initially only in those cells that are synthesizing deoxyribonucleic acid (DNA) in preparation for mitosis (*S* period). Since granulocytes eventually reach a stage of maturation in which mitosis does not occur, some cell types, for example, metamyelocyte, will become labelled only with the passage of time. Labelled metamyelocytes appear within 3–4 h after injection of tritiated thymidine; the percentage of labelled cells then increases linearly for a few hours to a plateau followed by a second rise after 14 h. The results are given in Fig. 1.

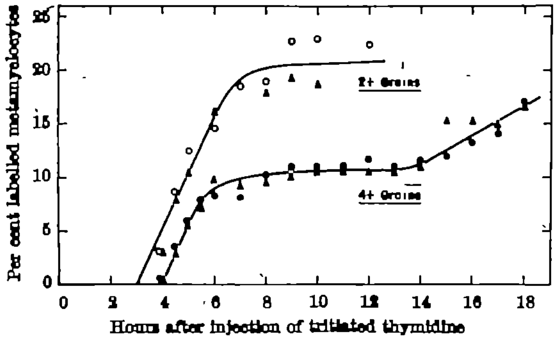

Fig. 1. Initial pattern of labelled metamyelocytes after injection of tritiated thymidine. (Each point is derived from enumeration of 1,000 metamyelocytes; triangles, dog *A34C*; circles, dog *A34E*)

It will be noted that the initial rate of increase of labelled metamyelocytes seems to be the same whether the autoradiographic analysis includes cells with 2 grains or more (2+) or only cells with 4 grains or more (4+). The linear increase extends over about 4 h with 2+ cells and 2 h with 4+ cells; it begins earlier and persists longer in the former instance. These results suggest that the more lightly labelled cells may be derived mainly from myelocytes which were near the beginning or end of their DNA synthetic period, while the more heavily labelled cells may be derived from a cohort near the middle of the *S* period. If this is so, the rate of uptake of thymidine must increase to a maximum around the middle of the *S* period and then decrease. The period of linear increase of 2+ metamyelocytes approximates 4·5–5-h duration of the myelocyte *S* period[4]; the agreement would perhaps be even closer if the progeny of myelocytes with less than 4 grains, which would appear as metamyelocyte false negatives, were included. The close correspondence of the duration of the *S* period and of the initial increase in labelled metamyelocytes indicates that there is little variation in the transitions from myelocyte DNA synthesis to myelocyte mitosis to metamyelocyte. A second rise in labelled metamyelocytes occurs some 10 h after the first increase. The rate of increase is less at this time, possibly because of the variation in the period preceding DNA synthesis, and also because of further dilution of the label by mitosis with resulting increase in false negatives. The 10-h interval may be a reflexion of the minimum duration of the myelocyte generation cycle.

Since the initial rate of entry of metamyelocytes is about 5 per cent per hour (Fig. 1), the turn-over or transit time would be 20 h. Labelled band cells were not seen even at 18 h after injection of tritiated thymidine, which means that the minimal transit time must exceed 15 h. It is noteworthy that a 20-h transit time was also obtained in earlier work by comparison of the time of appearance of label in metamyelocyte and band cell[1]. The initial rate of appearance of labelled metamyelocytes was considerably less in the latter instance, probably because insufficient thymidine was given to label all the myelocytes in synthesis of DNA. Since in the earlier investigation only about half the myelocyte mitoses were labelled during the first several hours after injection of tritiated thymidine, labelled and unlabelled cells must have entered the metamyelocyte compartment at the same time.

The magnitude of the metamyelocyte influx should correspond to the myelocyte efflux, assuming that few cells die or otherwise escape from the proliferating compartments. The initial labelling index of cells capable of mitosis and the duration of the *S* period provide a rather precise estimate of the birth or proliferation rate. This estimate will not be influenced by the possibility that: (1) all cells of a given type may not divide even though all may be capable of division; (2) the morphological boundaries of a given cell type may not include a complete generation cycle, that is, from the end of one mitosis to another. Some 37 per cent of myelocytes are labelled (2+ grains) a half-hour after injection of tritiated thymidine which, with an *S* period of 5 h, corresponds to a birth rate of about 7·5 per cent per hour. Since the metamyelocyte turnover is 5 per cent per hour, and the relative distribution of myelocytes to metamyelocytes in the marrow smear is 1 to 0·75, this means that for every 7·5 myelocytes that are born, only 3·75 myelocytes are transformed to metamyelocytes.

Cells are also entering the myelocyte compartment, and hence the myelocyte efflux must be greater than the myelocyte proliferation rate in the steady state with constant population. If we assume that all myeloblasts and promyelocytes eventually become myelocytes, the myelocyte efflux will be given by the sum of the proliferation rates of myeloblast, promyelocyte and myelocyte plus the presumed stem cell efflux (myeloblast influx). The latter is an indeterminate quantity at present, but it is probably very small relative to the succeeding fluxes. 40 per cent of myeloblasts, promyelocytes and myelocytes as a group are labelled at a half-hour after injection of tritiated thymidine; thus, the combined birth-rate with a 5-h *S* period is 8 per cent per hour. The proportional distribution of this group of cells to metamyelocytes is 1 to 0·6 and on this basis the relative efflux from the proliferating compartments would be 8 and the metamyelocyte influx 3. Whether we consider only the myelocyte proliferation rate or the approximate total myelocyte efflux, the results indicate a substantial 'over-production' or 'ineffective' granulocytopoiesis. A similar conclusion can be reached independently by comparing the expected yield after mitotic doubling of myelocytes labelled initially with 4 grains or more to the number of metamyelocytes with 2 grains or more. We can infer from the *S* period and the metamyelocyte appearance curve that all labelled myelocytes will have completed mitosis by 8 h after thymidine injection.

If only a part of the granulocyte production flows into the metamyelocyte compartment, it should be possible to account for the excess cells. Apropos of this, there is an increase in the percentage of labelled myelocytes during the first several hours after injection of tritiated thymidine. It is difficult to estimate the increase as long as some labelled cells are still undergoing mitosis. However, when myelocytes with 8+ grains at 0·5 h (21 per cent positive) are related to myelocytes with 4+ grains at 8 h after injection of tritiated thymidine (30 per cent positive), there is a 40 per cent increase. A similar increase does not occur in myeloblasts and promyelocytes. Thus, there is an appreciable 'sink' in the myelocyte compartment for accumulation of labelled cells. It follows that there must be a substantial number of myelocytes that do not participate in mitosis, but rather that are in a transitional phase prior to their loss in some way other than maturation to metamyelocyte. The transition from myelocyte to metamyelocyte requires about 1 h (3-h appearance time less 2 h for post-S period and mitosis); however, this could not be a factor in the accumulation of labelled myelocytes 8 h after thymidine administration. A prolonged myelocyte–metamyelocyte transition, postulated in our earlier experiments[1], would be inconsistent with the present finding that the initial rate of entry of labelled cells into the metamyelocyte compartment is sufficient to account for its turn-over. It is of interest that there is no evidence of metamyelocyte attrition; labelled metamyelocytes can be accounted for afterwards as labelled band cells[1].

Others have alluded to the possibility of some 'ineffective' erythrocytopoiesis[5,6] and the fact that 'ineffective production' occurs in the case of the granulocytes is perhaps not too surprising. The myelocyte overproduction cannot be attributed to possible toxicity from incorporated tritium[3] or to possible stimulation by thymidine[7]. If either of these factors were of consequence, this should be apparent in the rate of appearance of labelled metamyelocytes; the metamyelocyte turn-over is consistent with data obtained in other ways and after other doses of tritiated thymidine. It should be pointed out that this work was performed on young dogs and, conceivably, the degree of overproduction could vary with age. We are inclined to think that the so-called 'ineffective' granulocytopoiesis represents an important facet of granulocyte regulation. Flexibility of the granulocyte system could be brought about by adjustment of the balance of 'effective' and 'ineffective' production. The population relationships and their regulation will be discussed in greater detail elsewhere[8].

This work was carried out under the auspices of the U.S. Atomic Energy Commission.

A PRESUMED OBSTACLE TO MAMMALIAN POLYPLOIDIZATION

By YNGVE MELANDER

Institute of Genetics, University of Lund, Sweden

THE sex of *Drosophila* is determined by ratios between autosome sets and X's. The Y lacks sex determining genes. From this Muller[1] inferred that the sex chromosomes might be an obstacle to polyploidization in animals by virtue of the difficulty in maintaining the foregoing ratio.

Contrary to its inertness in *Drosophila*, the mammalian Y chromosome has a strong male-determining effect[2–4]. Still, the ratio of autosomal sets to X chromosomes ($A : X$) might complicate polyploidization due to the presence of sex chromatin or Barr bodies in female somatic interphase cells.

The transformation alternately of one paternal or one maternal X of the female embryo cells into the sex chromatin[5–7] is initiated during early embryogenesis by anaphase chromatid tension[8,9] due to pseudo-chiasma formation on one of the X's.

Most presumably, the X or the part of it which constitutes the sex chromatin is genetically inactivated[5–7]. This implies that the female zygote and a few subsequent cell generations have two active X's, but the somatic cells of later cell generations, only one. Thus, the somatic ratio of diploids would approach $2A : 1X$ in both sexes.

The present problem mainly concerns the resulting gene balance in the soma. In females this balance is the result of the embryonic X inactivation. Consequently, the theories trying to explain how many X's get inactivated should not take endopolyploid somatic cells as models. Such polyploid cells might have originated at a later stage and would represent the statically balanced situation of their predecessors. The events recorded under II (Table 1) are in agreement with all the balance theories proposed[9–12].

The resulting somatic $A : X$ ratio of polyploids perhaps would be $nA : 1X$ because in diploids supernumerary X's are transformed into sex chromatin. However, it is not definite that only one X of the polyploid would be active. Possibly, the gene ratio of the zygote and the succeeding few cell generations before the soma is formed determines whether the inactivation process starts or not. One could expect that the events always start at or below the level $A : X = 1$ and stop at $A : X = 2$, because these levels are characteristic of normal diploids. The formation of sex chromatin within presumably haploid $1A : 1X$ embryos[9] is in agreement with the supposition about the starting level. The haploids, however, do not tell us anything about a final ratio.

There are several instances of polyploid embryos reported from experimental mammals[13,14] but the lack of information concerning their sex chromosome conditions leaves the imaginable courses of X chromosome inactivation only to conjecture.

Table 1. ANTICIPATED X-ACTIVITY IN ZYGOTE, GERMLINE, SOMA BEFORE X CHROMOSOME INACTIVATION AND IN SOMATIC CELLS FROM EMBRYOS AT VARIOUS PLOIDY LEVELS

Diploidy of one of the gametes (restitution nuclei at one of the two meiotic divisions) or doubled zygotes is considered. (Normal ratios and verified numbers of sex chromatin bodies in italics)

Zygote All X's active	Germline, and soma before X inactivation All X's active		Soma after X inactivation (I) Inactivation of X's approaching the ratio at which all but one X's are inactivated			(II) Inactivation of X's approaching the normal diploid ratio $2A : 1X$		
Chromosome complement	$A : X$	Sex chromatin bodies	Genotype X, active (X), inactive	$A : X$	Sex chromatin bodies	Genotype X, active (X), inactive	$A : X$	Sex chromatin bodies

$4A+2X+2Y$	*2 : 1*	0	$4A+X+(X)+2Y$	4 : 1	1	$4A+2X+2Y$	*2 : 1*	0

* (ref. 9) † (ref. 20) ‡ (ref. 11)

To my knowledge there are three reports of human beings containing a majority of triploid cells in which the sex chromosome constitution were analysed[15-17]. In each case the triploid cells all had the constitution $3A : XXY$. In two cases the embryos were spontaneously aborted at an early stage[16,17] and in one case, where an abnormal young male patient was examined, he was found to be a mosaic composed of triploid and diploid cells[11]. This human triploid–diploid mosaic is another example of what has been found in a male rabbit[18] and pig[19]. It is at present possible to understand the principles for the origin of triploid–diploid mosaics in mammals[14], and the evidence of their post-embryonic existence is accumulating. However, newly arisen pure polyploid mammals have not so far been found as adults.

The events connected with the X chromosome activity in the zygotes, and at the subsequent differentiation of somatic cells from the germline, are summarized in Table 1.

Within a triploid–diploid mosaic there would be a selection on the somatic level against triploid cells, because they are unbalanced. One of the possible sources of this unbalanced condition may be the relation between active X and autosomal genes. The lack of a sex chromatin body[11] or the presence of one[20] has been reported in these cells. This would imply that either two or one genetically active X functions respectively. From this follows that the two expected $A : X$ ratios in the $3A : XXY$ triploid cells, somewhat deviating from the normal 2 : 1 ratio, are realized. Possibly, cells with one and two active X's have a different survival value. It would contribute to a further understanding of the problem to know the viability of a human triploid–diploid mosaic, in which the triploid cells display one sex chromatin body instead of none.

It seems very probable that the diverging relationships between active sex chromosomal and autosomal genes, which would result in the somatic cells of pure triploids, cause the serious disturbances and lethality which seems to be their characteristic[14].

Female and male tetraploids would be normally balanced both in their germlines and their somatic cells, provided the inactivation of X's occurs according to the second possibility scheduled in Table 1, which is the most probable event. However, if all but one of the X's are inactivated in accordance with the first possibility scheduled, the balance in the somatic cells of tetraploids would be very abnormal. Of course, the tetraploids may have too many chromosomes to function very well even if their $A : X$ ratio is in accordance with the one in diploids, both in germline and soma.

If the present assumptions are correct, they would imply that occasional tetraploids of both sexes resulting from zygote doublings in mammals have a fair chance to survive. At least there should not be any obstacles due to $A : X$ imbalance either in the germline cells at very early embryonic life or later on in the soma. The mammalian pure triploids, however, would have a minimum chance of survival because of a necessarily abnormal chromosome balance in the early embryonic cells of males and in the soma of both sexes.

Thus, the newly obtained knowledge about 'dormant' X chromosomes would explain why mammalian triploids have not been able to participate in the establishment of tetraploidy.

ELASTASE PRODUCTION BY MICRO-ORGANISMS

By Dr. ANTHONY J. SBARRA, Dr. JOHN S. BAUMSTARK, Dr. ROBERT F. GILFILLAN
and Dr. WADI A. BARDAWIL

Department of Pathology and Medical Research, St. Margaret's Hospital and Tufts University Medical School, Boston 25, Mass.

BECAUSE of the possible implication of pancreatic elastase in the aetiology of vascular diseases[1,2], it was felt that elastase derived from sources other than the pancreas might provide interesting comparative characteristics. Thus, in conjunction with a study of pancreatic elastase and its serum inhibitor, under way in this laboratory, our attention was turned to the microbial flora of soil. Soil is a source known to provide micro-organisms capable of breaking down all natural substrates. This article describes some of the characteristics of an elastolytic enzyme isolated from a fungus obtained from soil. Also, the possible implication of this elastase-producing fungus in the etiology of temporal arteritis is discussed.

Elastin, prepared according to the method described by Gilfillan *et al.*[3], was used in the assay system. An agar medium containing only elastin, agar and inorganic salts was prepared as shown in Table 1. About 1 g of soil obtained from a flower bed in the hospital grounds was dispersed in 99 ml. of sterile distilled water. A 0·1-ml. aliquot was spread over the entire surface of elastin agar plates which were then incubated at room temperature (22°) and at 37° for a 3–5 day period. Isolates which showed clearing of the elastin were picked and restreaked on elastin agar medium for pure culture clones.

A 3–5-day culture of one of the organisms grown in Fildes tryptic digest broth (BBL), afterwards identified as *Streptomyces flaveolus*, was used for the preparation

Table 1. COMPOSITION OF ELASTIN MEDIUM*

Components	Amount of components in stock solution	Volume of stock solutions for 100 ml. of complete medium
Inorganic salts *A*	25 g

of crude elastase. The mycelial mat was removed by filtering through 3–4 pads of cheese-cloth. Extracellular elastase was purified by fractionation with ammonium sulphate. Ammonium sulphate was added to 60 per cent saturation and precipitation was allowed to proceed overnight at 2°–5°. The resulting precipitate was collected after centrifugation at 12,000*g* for 45 min. It was then suspended in carbonate buffer *p*H 8·4 and dialysed against this buffer overnight before assay.

The crude intracellular enzyme was prepared by grinding the mycelial mat with alumina (80–200 mesh, Fisher Scientific Co.). About 2 vol. of carbonate buffer, *p*H 8·4, was added to the extract and allowed to stand in the cold for 1 h. The alumina was removed by centrifugation at 2,000*g* for 15 min, and the supernatant was clarified further by centrifugation at 20,000*g* for 60 min. The resulting clear supernatant was collected and served as a source of crude intracellular enzyme. Both intra- and extra-cellular enzyme was assayed by the plate technique, as described by Sbarra *et al.*[4,5], and nepholometrically, as described by Gilfillan *et al.*[6]. The crude intracellular enzyme was used in all our studies. The extracellular enzyme was found active both on plates and nephelometrically. These results will be reported later.

Normal human serum was obtained from healthy personnel of the laboratory and tested for inhibitor as previously described[3]. A number of mice and guinea pigs, weighing approximately 20 g and 350 g respectively, were injected intraperitoneally with a 5-day culture of *Streptomyces flaveolus*. The animals were killed at intervals, from day 1 to day 150, after challenge, and histological sections of liver, kidney, blood vessels, spleen, intestine, skin and lungs were prepared. Two sets of slides were made, one was stained with hæmatoxylin and eosin, and the other with periodic acid–Schiff stain.

Five different organisms were isolated from soil which have the ability to hydrolyse elastin. Two of these have been placed in the genus *Streptomyces*; one has been completely characterized and classified according to *Bergey's Manual of Determinative Bacteriology*[7], as *Streptomyces flaveolus*, but the other has not yet been assigned a species designation. A yellow pigmented organism, capable of digesting elastin and belonging to the genus *Flavobacterium* was also isolated. In addition, a mould and a Gram-positive spore-forming rod were also observed to digest elastin and subsequently identified as *Aspergillus niger* and a *Bacillus* sp. respectively.

The elastolytic activity of *Streptomyces flaveolus* on agar containing elastin is shown in Fig. 1.

The results obtained when the crude intracellular enzyme was allowed to hydrolyse elastin, in the absence and presence of serum, are shown in Fig. 2. It can be seen in Fig. 3 that the optimum elastolytic activity occurs at 30°. Table 2 shows that the enzyme is completely inactivated by heating for 30 min at 54°. Such treatment effectively inhibits hydrolytic activity but subsequent incubation at 37°, in the presence of the substrate, restores activity so that at 24 h it is equally as active as untreated enzyme. Reactivation does not occur following treatment at 100° for 15 min.

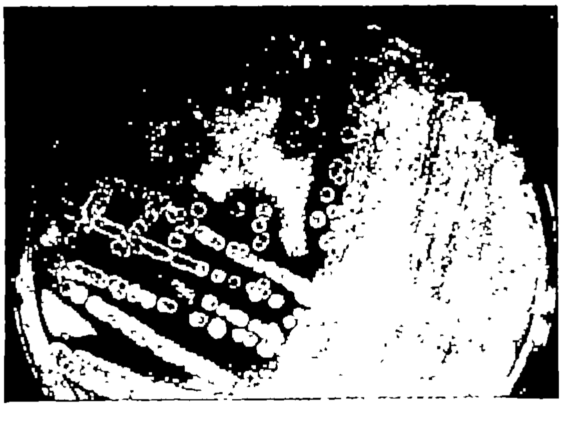

Fig. 1. Elastin agar plate inoculated with *Streptomyces flaveolus*. Afterwards incubated at room temperature (22° C) for 72 h. Clearing around colonies due to liberation of elastase

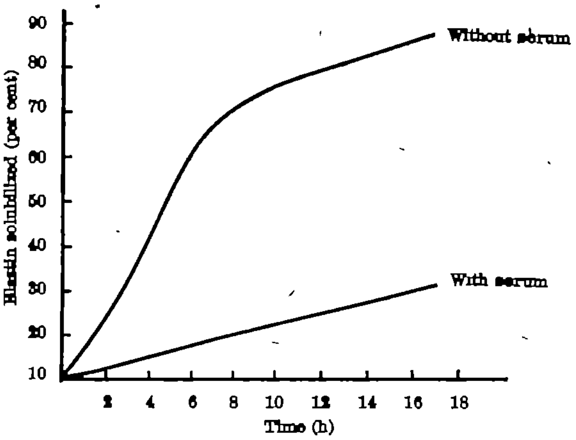

Fig. 2. Effect of *Streptomyces flaveolus* elastase on elastin in the absence and presence of serum. The reaction was followed nephelometrically in a Bausch and Lomb Spectronic 20 colorimeter at 550 mμ. The reaction mixture consisted of 0·5 ml. of elastase (0·9 mg protein), 24 mg elastin was made to 4·0 ml. with carbonate–hydrochloric acid buffer *p*H 8·4, ionic strength 0 05. All reactants were warmed to 37° and enzyme was added at zero time

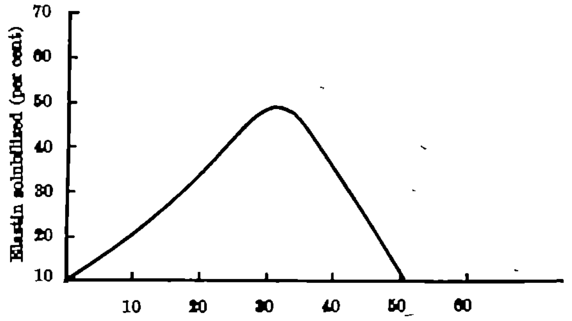

Fig. 3. Effect of temperature on solubilization of elastin by *Streptomyces flaveolus* elastase. Substrate-disappearance was measured at half-maximum velocity in a system containing 0·9 mg enzyme protein

The only pathological changes seen so far have been the appearance of granulomas in the liver and lungs of both mice and guinea pigs that had previously been injected with a 5-day culture of *Streptomyces flaveolus* twice weekly for one month. Histological sections of liver and lungs of autopsied guinea pigs showed the presence of acidophilic homogeneous spherules and elongated structures which gave a positive reaction to the periodic acid–Schiff stain. These structures are tentatively considered as spores or mycelial fragments. Animal tissues from uninfected animals did not reveal these structures.

The finding that different micro-organisms have the ability to produce elastase is not new, but the significance of such findings has received little, if any, attention. Horton and Magath[8,9], in an investigation concerned with

the ætiology of temporal arteritis, were able to isolate an 'Actinomyces' from resected temporal arteries in two out of seven temporal arteritis patients studied. After limited bacteriological studies they concluded that these organisms were laboratory contaminants, and thus were not associated with ætiology. The organism involved could have been a *Streptomyces*, a common soil organism, according to current classification. Inasmuch as five of the seven patients examined were farmers, the organisms could have gained entry through the mouth. It is also possible that dental procedures might permit entrance of an otherwise non-pathogenic organism. The fact that *Streptomyces* produces elastase and since mycelial fragments were observed at biopsy may indicate a primary or secondary association of these organisms in the elastic tissue destruction (modification) observed in this disease. Further, these observations suggest that epidemiological studies in this disease may prove fruitful.

In limited animal studies, so far, we have been able to detect granulomas in the livers of mice and guinea pigs injected with *Streptomyces flaveolus*. It has also been possible to stain mycelial-like fragments in the liver of guinea pigs and to recover, on occasion, organisms from the livers of injected mice. No other pathological changes have been detected so far. The significance of the liver and lung granulomas is, as yet, unknown. The possibility that elastase-producing micro-organisms may be associated with the ætiology of vascular diseases is intriguing and is at present under investigation.

The fungal enzyme, like the pancreatic elastase, is inhibited by serum. Mandl and Cohen[11] have reported a bacterial elastase produced by *Flavobacterium elastolyticum*, that is not inhibited by serum. This bacterial enzyme differs from that described since it was found to have optimal activity between 50° and 55°. The fungal enzyme has a temperature optimum of 30°. Thus, it appears that these two enzymes are different in at least two respects. On the other hand, the fungal enzyme appears similar to the pancreatic elastase in respect to serum inhibition and temperature optimum. The significance of these findings is unknown.

The reactivation of the enzyme by incubation at 37° is of interest. Perhaps the enzyme chain is inactivated at 54° by a folding phenomenon, and subsequent incubation at 37° results in unfolding with a concomitant restoration of activity. Investigations are under way to further purify the enzyme.

BIOCHEMICAL ANALYSES OF THE CARCASS IN LETHAL STAPHYLOCOCCAL INFECTIONS OF MICE

By SHIRLEY S. LINDELL, DR. IAN M. SMITH, DR. JOSEPH I. ROUTH and MARGRIETA DELLE

Departments of Medicine and Biochemistry, University Hospitals and State University of Iowa, Iowa City

In previous investigations[1] we found that mice killed by injections of virulent staphylococci show a high blood concentration of transaminase, alkaline phosphatase and inorganic phosphorus associated with a low sodium. There was some indication also of less-definite decreases in the blood levels of sugar, carbon dioxide and cholesterol. It appeared necessary to extend the work to see if the alterations of the blood were coincidental or an essential part of the mechanism of death. In order to avoid conclusions from biochemical changes restricted to the blood stream, we have studied the total biochemistry of the animal body.

The hæmolytic, coagulase-positive Smith strain of *Staphylococcus aureus*, the properties of which have been published previously[2,3], was used. The mice used were Carworth Farms (New City, New York) white, Swiss males. The animals weighed 15–18 g and were given food and water *ad libitum* before examination. Mice were inoculated with a heavy dose (0·1 c.c. = 10^9 organisms) intraperitoneally, as we have shown that the dose of organisms (above a certain minimum quantity) and route of infection were not important in the production of death in mice from staphylococcal infections[3]. Homogenates of whole mice (less skin, tail and feet—which did not blend[4] and gut to avoid Gram-negative organism contamination) were made by adding the carcass to 50 ml. of chilled distilled water and grinding for ½ min at slow speed and 2½ min at high speed[3,4].

The carcass homogenates made at death were transferred to the biochemistry laboratory and the determinations were made by standard methods. Sodium fluoride (10 mg/c.c.) was added to prevent enzymatic degradation of the glucose before analysis.

Biochemical values for normal and infected Carworth Farms white mouse carcasses are given in Table 1. A comparison of the results of the normal and intraperitoneally infected mice show statistically significant differences ($P \leq 0{\cdot}05$) in sugar, total protein, cholesterol, inorganic phosphorus and transaminase (Table 1).

Significant and comparable chemical changes in glucose, inorganic phosphorus, transaminase and cholesterol are found in the blood and carcass. The blood proteins show a decrease parallel to the carcass proteins but the extent of the change is not significant[1]. If it is assumed that inflammation destroys the semipermeable membranes of the body leading to an adynamic equilibrium of intra- and extra-vascular substances, then the changes in alkaline phosphatase in the blood are easily explained. Possibly a similar mechanism explains the discrepancies in the carbon dioxide values. Further study is needed to correlate the sodium loss in the carcass with the sodium loss in the blood.

Two additional strains of *S. aureus* were used for challenging the same strain of mice. Analysis of the biochemical results detailed in Table 1 showed no discrepancies from the conclusions reached with the Smith strain.

Limited studies of carcass biochemical values have been completed for other routes of inoculation (Table 2). Good correlation was observed in all values except inorganic

phosphorus when the results were compared with those obtained following intraperitoneal infection.

Additional significance can be given to these chemical findings by showing a steady trend from the time of infection to the time of death. Animals have been studied at hourly intervals after intraperitoneal challenge with *S. aureus* Smith and a significant trend was shown (Fig. 1) for glucose.

To differentiate between the consumption of glucose by *S. aureus* and consumption by the mouse host, an *in vitro* investigation was made. Mice were injected with *S. aureus* in the usual manner and immediately killed and the carcasses were ground. After an aliquot was taken for glucose determination, the homogenates were placed in the 37° C incubator. Glucose determinations were made every hour for 6 h and the results were compared with those obtained from the *in vivo* study (Fig. 2). It is evident that microbial consumption of glucose does not explain the loss of glucose from the carcass at death from staphylococcal infection. Normal uninfected carcasses placed in the incubator and sampled at intervals did not change significantly in glucose content.

Other studies in our laboratory have shown that animals infected with the Smith strain of *S. aureus* ($10^9 = 0·1$ c.c. intraperitoneally) can regularly be cured by 400 mgm/kg of penicillin *G* if the drug is given subcutaneously 1 h after infection[8].

Hourly glucose determinations were made to see if glucose-levels of staphylococcal infected mice would return to normal after treatment with penicillin. It may be seen in Fig. 3 that although there is an initial fall in glucose, a gradual rise is evident although not as marked as we had expected.

Similar challenge with heat-killed (80° C for 30 min) Smith strain of *S. aureus* given intraperitoneally revealed, in addition to the changes found with live virulent *S.*

aureus, significant differences in the values for urea nitrogen, creatinine, uric acid, carbon dioxide, chloride sodium, alkaline phosphatase and acid phosphatase when compared with the values for healthy animals (Table 1).

Three live virulent human strains of *S. albus* (*S. epidermidis*—coagulase negative) obtained from patients (cases 6, 7, and 9, ref. 5) were inoculated in large doses (0·1 c.c. = 10^{10} intraperitoneally in mice. The biochemical values for each of the strains were virtually identical so that all the values were analysed as a group and compared with controls. The findings were similar to those with live *S. aureus* organisms except that creatinine, uric acid and carbon dioxide values were significantly decreased compared with the controls (Table 1). Inorganic phosphorus was not significantly elevated.

The excessive biochemical changes with heated *S. aureus* and *S. albus* may be caused by degradation products released by heat or by the destruction of *S. albus* by host phagocytes.

Because of the reproducible fall in glucose values, sodium lactate should, in theory at least, be beneficial to the infected animal by providing, as pyruvate, an available source of glucose replacement or as blood lactic acid a potential source of liver glycogen.

It has been observed by Berry *et al.*[8] that certain endotoxins will block the conversion of blood glucose to liver glycogen, thus forcing the conversion to muscle glycogen instead. Therefore, the only pathway to liver glycogen is by way of blood lactate. If a severe energy requirement is pressed on an organism without simultaneous increase in respiration, this requirement is largely met by enhanced glycolysis by way of blood lactate.

Preliminary evidence from biochemical findings in patients dying from staphylococcal disease indicates carbohydrate derangement and protein depletion[9].

We have shown previously that glucose given orally was deleterious to fasting mice infected intravenously with staphylococci[10]. This effect could only be detected during the initial phase of infection in fasted animals and in mice that survived infection; those receiving glucose during the fasting period seemed better able to destroy staphylococci than those receiving only saline as drinking fluid.

Studies to be detailed elsewhere[7] show that treatment with glucose, 1/6 M sodium lactate or inorganic phosphorus will significantly lengthen the survival time of infected mice whereas mouse plasma proteins and transaminase are deleterious. Cholesterol treatment was ineffective.

We conclude that the severe derangements of carbohydrate metabolism in mice dying from severe staphylococcal infections are part of the death mechanism as survival time in infected animals is significantly increased by appropriate replacement.

This investigation was supported by research grant No. E4046 of the U.S. Public Health Service, National Institutes of Health and the Iowa Thoracic Society. We thank Dr. Elia Ch. Hazard and Mrs. Fern Hulting of the Infectious Disease Division Laboratory and the personnel of the Clinical Biochemistry Laboratory for their assistance. Mrs. J. F. McTavish made the statistical analyses for us.

PASSIVE AGGLUTINATION TESTS

Bismuth Tannate Test

THE passive hæmagglutination test described by Boyden[1] as well as variations of this method find widespread application as sensitive procedures for the detection of antibodies. Collodion and latex particles have been used instead of the tannic acid-treated red blood cells. However, laborious techniques and unsatisfactory antigen binding limited the use of these particles.

In this communication the use of bismuth tannate particles for the passive agglutination test is described.

Bismuth tannate is a brownish yellowish powder containing 40 per cent bismuth monoxide, insoluble in saline solutions. The bismuth tannate particles are of varying size and before use the larger particles are removed. This is performed by preparing a suspension of 2 g of bismuth tannate in 10 ml. of a 0·85 per cent sodium chloride solution. This suspension is then homogenized for 15 min in a standard homogenizer at high speed. It is next transferred to a test tube, left undisturbed for 30 sec before decantation into another test tube. The larger particles of bismuth tannate remaining in the first tube are discarded. The suspension is centrifuged for 3 min at 2,000 r.p.m. This stock suspension may be kept in the refrigerator for many weeks. For use 0·3 ml. of the sediment are added to 9·7 ml. of saline.

Equal volumes (10 ml.) of the bismuth tannate suspension are added to an antigen solution in saline and kept at room temperature for 30 min with repeated shakings. The sensitized bismuth tannate particles are then washed three times in 15 ml. of saline to remove the unfixed antigen. After the third washing 10 ml. of saline are added to the antigen-coated bismuth tannate particles.

The antiserum dilutions in volumes of 0·2 ml. (in tubes 14 mm × 80 mm) are performed with a dilution of 1·5 per cent of normal rabbit serum in saline. To each tube one drop of antigen-coated bismuth tannate particles is added. The tubes are shaken vigorously for 3 min and placed in a refrigerator for 2 h. After 2 h the tubes are again vigorously shaken and left at room temperature for at least 4 h before reading results. A second reading is performed after overnight incubation of the tubes in the racks without any shaking. Special care must be taken in order not to disturb the suspension in the tubes. It was found practicable to place the tubes in clear plastic racks on a glass surface with a mirror underneath at an angle of 45°. In such a way the sedimentation pattern could be observed in the mirror without any handling of the tubes.

As the pattern of the bismuth tannate sedimentation is different from that of the tannic acid-treated erythrocyte passive hæmagglutination, it was found practicable to run a parallel control of every experiment by adding the antigen-coated bismuth tannate particles to dilutions of a normal serum. This precaution is unnecessary after gaining some experience when one tube of the 1·5 per cent normal rabbit serum in saline with the antigen-coated bismuth tannate particles serves as control.

The negative controls and the negative higher dilutions of the antiserum showed a regular sedimentation of the bismuth tannate particles either in the form of a ring with or without a central point or as brownish coating of the whole bottom of the tube. The positive results are recognized by the sedimentation of the bismuth particles in an irregular thick denticular ring form, as a coarse brownish bottom or merely as a ring with a more pronounced design. These patterns depend on the antigen–antibody system used and on the concentration of these components. Therefore, when working with an unknown system, positivity must be appreciated only by comparing every tube with its negative control. The test was performed with different antigen–antibody systems; it did not require any buffers, and gave very satisfactory results also with the inhibition technique. The inhibiting antigen was added to the antiserum 30 min before the addition of the bismuth tannate antigen-coated particles. The coating of the bismuth tannate particles with non-protein antigens was unsuccessful. Some systems gave better results with the bismuth tannate particles; others, however, were superior when the tannic acid hæmagglutination test was utilized. The most probable explanation for these discrepancies are differences of antigen coating in the two techniques. Bismuth tannate may be prepared by allowing an aqueous solution of $Bi(NO_3)_3 . 5 H_2O$, slightly acidified by HNO_3, to react with an alcalic solution of tannic acid. The yellowish precipitate obtained at room temperature was washed five times with large amounts of saline and thereafter dried. The residue after drying was thoroughly grounded and the powder obtained used as indicated above.

This test was developed in connexion with an investigation of immunological aspects of corneal transplantation and supported by grant *NB* 02018–04 from the U.S. National Institutes of Health.

Barium Sulphate Test

COLLODION[1], bentonite[2], tanned red blood cells[3], latex[4] and bismuth tannate (preceding communication) have been used for the detection of circulating antibodies in passive agglutination tests. These particles serve as vehicles for the antigen which is in solution or a suspension of very minute particles.

In the presence of the corresponding antibody the antigen-coated particles are agglutinated, precipitated or sedimented in an altered pattern.

As the pattern of sedimentation may easily be disturbed by very slight shaking, it is convenient to place the tubes in clear plastic racks on a glass surface with a mirror underneath at an angle of 45°. In this way results are read through the mirror without handling the tubes.

This communication describes the use of barium sulphate for a passive agglutination test. The barium sulphate passive agglutination method provides an additional, very simple, rapid and sensitive method for the detection of circulating antibodies.

Equal volumes of 3 per cent barium sulphate suspension in saline and antigen are mixed and shaken. After 2-min contact at room temperature, the sensitized barium sulphate particles are washed three times in saline. The packed sediment obtained is resuspended in normal rabbit serum 10 per cent in saline so as to regain the original 3 per cent concentration.

One drop (0·05 ml.) of the sensitized barium sulphate suspension is added to each tube (14 mm × 80 mm) containing 0·2 ml. of the antiserum dilutions. The dilutions are performed in normal rabbit serum 5–10 per cent in saline. For every antigen–antibody system the optimal concentration of normal rabbit serum within a range of about 5–10 per cent must be determined, in order to get a completely negative control. The tubes are shaken vigorously and placed at room temperature. The pattern of the sedimentation of the barium sulphate particles is examined after 30 and after 60 min. For another reading the tubes may be thoroughly shaken and the pattern of sedimentation is again obtained.

As control, one drop of antigen-coated barium sulphate suspension is added to 0·2 ml. of the diluent. A negative result is indicated by sedimentation in a form of a regular ring (Fig. 1, right tube). The strong positive tubes show sedimentation in the form of denticular curved lines (Fig. 1, five left tubes) and the intermediate positive tubes show no well-defined distribution.

This test has certain advantages over other passive agglutination methods. It does not require early washings or pre-treatment with tannic acid. The incubation periods are also very short. The interaction between the barium sulphate and the antigen is very rapid and so is the sedimentation of the sensitized particles. Results may be read after 60–90 min from the beginning of the test. The simplicity and the fact that no buffers or expensive materials are needed make it cheap and easy to perform even in small laboratories.

The barium sulphate particles are stable; the connexion between them and the antigen is firm. The coated particles may be preserved for at least 14 days before their addition to the antiserum. The sedimentation patterns, both the positive and the negative results, may also be preserved for days without changes.

No absorptions of the antiserum or of the normal rabbit serum are needed as the barium sulphate particles are antigenically inert. This method may therefore replace the tannic acid hæmagglutination test in cases where the antiserum contains anti-red blood cell antibodies.

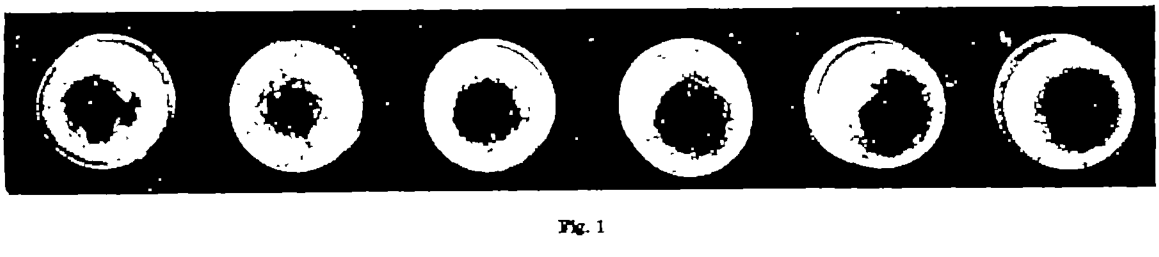

Fig. 1

The sensitivity of the passive barium sulphate agglutination test is greater than that of agar-gel diffusion, precipitation or direct agglutination techniques. In some antigen–antibody systems it is, however, somewhat less sensitive than the tannic acid hæmagglutination test, while in other systems the sensitivity is even greater than that of the tannic acid hæmagglutination test.

The passive barium sulphate agglutination test was performed with the following antigens and their corresponding antibodies: (1) whole human serum—rabbit anti-human serum; (2) human γ-globulin—rabbit anti-γ-globulin serum; (3) chorionic gonadotropin—rabbit anti-chorionic gonadotropin serum; (4) human thrombocyte extract—rabbit and monkey anti-human thrombocyte serum; (5) human leucocyte extract—rabbit and monkey anti-human leucocyte serum; (6) snake venom (*Vipera*)—horse anti-snake venom serum.

In all these systems no false positive results were encountered.

BLOOD COAGULATION IN ARTERIOSCLEROTIC RATS

By PROF. BERNARD C. WEXLER and DR. MARK J. EPSTEIN

May Institute for Medical Research, Jewish Hospital of Cincinnati, and Department of Pathology, University of Cincinnati College of Medicine, Ohio

MALE and female rats exposed to the stress of repeated breedings spontaneously develop arteriosclerosis[1-3]. Microscopically, the arterial lesions demonstrate marked alterations in mucopolysaccharide ground-substance and connective tissue elements (Fig. 1). Duguid[4] and others[5] have emphasized the participation of abnormal coagulability of blood and thrombosis in the pathogenesis of arteriosclerosis. With this in mind, an investigation of the coagulability of blood in these arteriosclerotic rats was begun.

Virgins and discard breeder rats of approximately nine months of age were obtained from a commercial breeder (Sprague–Dawley). A total of 300 breeders were weighed, bled and then autopsied. At autopsy, the aortæ were examined for gross evidence of arteriosclerosis. All blood samples were taken by cardiac puncture under the lightest possible anæsthesia with ether. Blood was drawn into 5 ml. siliconized syringes (G.E. dry film *SC*–87). Needles were coated with 'Monocote *E*' (Armour). The whole blood clotting time was determined by the Lee–White method[6]. Prothrombin time was determined by the one-stage method of Quick[7], using Bacto thromboplastin. The foregoing procedure was also carried out in saline-diluted plasma (12·5 per cent). Dilution of excess of clotting factors present in blood makes possible the detection of more subtle quantitative changes. Recalcification time was utilized to demonstrate the presence of a circulating anti-coagulant in the blood of breeder rats. Anti-coagulant activity can be demonstrated by mixing plasma from the breeder rats with plasma from virgin rats which show a normal clotting time. The plasma was prepared from oxalated blood by centrifugation at 1,750 r.p.m. for 5 min. Samples containing 0·1 ml. of plasma were placed in clean 13 × 100 mm test tubes and incubated for 3 min at 37°. Since the recalcification time becomes shortened with prolonged incubation, it is important that the incubation period be standardized. Calcium chloride, 0·2 ml. (0·01 M), was added to the plasma. The tubes were tilted at 30-sec, 1-min, and at 20-sec intervals thereafter. The recalcification time was taken as the interval from the addition of the calcium chloride to the formation of a solid clot. To examine the effects of breeder plasma on the recalcification time of virgin rat plasma, 0·05 ml. quantities of breeder and virgin plasma were mixed and the changes in recalcification times were measured.

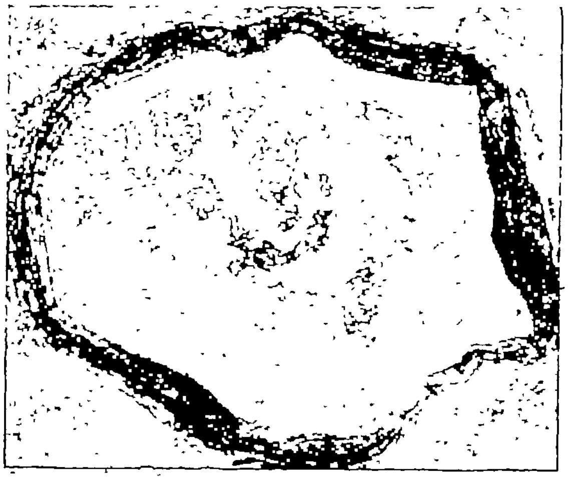

Fig. 1. Thoracic aorta of a repeatedly bred female Sprague–Dawley rat with severe arteriosclerosis. The dark black material in the photograph shows the heavy concentration of acid mucopolysaccharides in the disrupted ground substance of the arterial wall. (Hale stain, × c. 44)

At autopsy, the entire aorta (arch to iliac portion) was removed, dissected free of extraneous tissue including the adventitia, and blotted dry between filter paper. 1-g samples of aorta were collected from male and female breeders and from male and female virgin rats. The samples were homogenized in a Ten Broeck homogenizer and extracted with 25 ml. of distilled water. The samples were then exposed to ultrasonic vibration in a Raytheon sonic oscillator for 30 min at 1·25 amp and at maximum 'frying' noise to break up the complex of bound mucopolysaccharides. Next, the samples were boiled for 1 min to destroy the protein constituents, diluted to the original volume (25 ml.) and centrifuged for 5 min at 2,500 r.p.m. The supernatants were then lyophilized, dissolved in 3 ml. of distilled water, and frozen for storage. To facilitate the accurate measurement of the effects of aortic extracts on the clotting mechanism, the optical density was determined during the formation of a fibrin clot at 450 mμ (Coleman Junior spectrophotometer). A calcium chloride solution, 0·6 ml. of 0·01 M concentration, was added to a mixture containing 0·1 ml. plasma, 0·1 ml. extract, and 0·1 ml. distilled water, and placed in microcuvettes (10 mm int. diam.) which were fitted with microspace cuvette adapters. The time was noted, and readings taken at 10-sec intervals following the onset of the galvanometer deflexion. The changes in optical density were plotted against time. The intercept between two straight lines, one drawn through the initial plateau and the other drawn through that portion of the curve which shows a linear relationship between the rate of change of optical density and time, was taken as the end point. Control determinations were made in which 0·1 ml. of saline was substituted for the extract sample.

First, a comparison was made of the whole-blood clotting times of male and female non-atherosclerotic virgins and arteriosclerotic breeders. The results indicated that there was prolonged clotting in breeder rats when compared with virgins.

Next, the prothrombin times were investigated to learn if, in this factor, a similar relationship existed between virgin and breeder rats. The results indicated that there was no significant difference between the prothrombin times of virgin and breeder rats. Therefore, these results suggested that the active factor or factors producing the prolongation of clotting mentioned above might be among the variables which are not measured by Quick's one-stage prothrombin test. Such variables might be alterations in the concentration of factors V and VII, and heparin in quantities sufficient to interfere with prothrombin conversion or with the conversion of fibrinogen to fibrin by thrombin[6].

The next question was whether the prolongation of clotting could be due to the presence of a 'circulating anti-coagulant'. Six samples of breeder blood with prolonged clotting were individually added to six separate samples of virgin blood with normal clotting. An average of 54 per cent prolongation of the clotting time of virgin blood was demonstrated on addition of the breeder blood. Blood taken from virgin rats was added to other virgin blood as a control. No such prolongation was observed. This crude estimation of coagulability indicated that an unknown substance, present in the circulation of breeder animals but not in virgin controls, would retard the clotting of plasma. Further experiments were designed to delineate the nature and activity of this substance (or substances).

Breeder rats show a high concentration of mucopolysaccharides in the walls (Fig. 1) of their major arteries[3]. We became interested in the possibility that the intramural aortic mucopolysaccharides found in these arteriosclerotic rats may have anti-coagulant activity and might account for the prolonged clotting. Aortæ from male and female, virgin and breeder rats, were extracted as previously outlined. Blood samples freshly collected from virgin female rats were used as substrate. The effect of aortic extracts on the spectrophotometrically recorded clotting times was tested utilizing a pool of virgin rat plasma as a uniform substrate. The results are given in Table 1. The aortic extracts, each compared with the saline control, uniformly exhibited marked anti-coagulant activity. The average value of anti-coagulant activity of the virgin females was somewhat greater than that of the virgin males. The breeders exhibited the most profound anti-coagulant effect in extracts of their aortæ, that is, an average of 80 per cent.

Table 1. ANTI-COAGULANT ACTIVITY OF AORTIC EXTRACTS* ON PLASMA SUBSTRATE AS MEASURED BY THE TIME REQUIRED FOR THE FORMATION OF A CLOT

Source of aorta extracts (equivalent to 1 g fresh tissue)	Average of seven separate trials
Saline (control)	163†
Virgin males (no arteriosclerosis)	191
Breeder males (minimal arteriosclerosis)	231
Virgin females (no arteriosclerosis)	229
Breeder females (minimal to severe arteriosclerosis)	292

* To collect 1 g of virgin aorta required killing an average of 12 rats; for 1 g of breeder aorta, 7 rats.

† Time of clotting (sec) as measured by the spectrophotometric procedure.

In summation, the arteriosclerosis which develops in rats by repeated breedings is characterized by heavy accumulations of mucopolysaccharides (Fig. 1). The mucopolysaccharides, heparin and chondroitin sulphate B, are active anti-coagulants, and are found in the arterial wall[5]. If these aortic constituents were discharged into the blood stream, they presumably could materially alter the coagulability of the blood. Thromboses, although present in these animals, occur infrequently. The growth of atheromata as the result of the deposition of fibrin on intimal surfaces with subsequent endothelial overgrowth and eventual incorporation of the clot, as suggested by Duguid[4], does not appear to be applicable to these animals. It is interesting that prolonged clotting instead of accelerated clotting was found in these arteriosclerotic breeder rats. The initial observation that breeder plasma when added to virgin plasma produced prolonged clotting (54 per cent increase) has suggested the possibility that a circulating anti-coagulant is operative. Gore and Larky[7] and Dyrbye and Kirk[8] and Kirk[9] have demonstrated that animal and human aortic tissue contains an extractable anti-coagulating material which is mucopolysaccharide in nature. A search was made for a similar factor in these animals. Because of the difficulty of separating mucopolysaccharides from protein and other complexes, we resorted to exposure of the aortæ to ultrasonic oscillation. It was further necessary to boil these extracts to unmask the anti-coagulating activity. Tests of the unboiled extracts showed acceleration of the clotting process rather than prolongation, most likely due to the presence of tissue thromboplastic components and related substances.

All of the aortic extracts prepared in the foregoing manner demonstrated anti-coagulant activity. Statistically, analysis of variance of these results in Table 1 indicates that the physiological activity of the unknown factor is highly significant ($P = 0{\cdot}005$). The highest anti-coagulating activity was found in female breeder rats. It is suggestive that these are the animals which also showed the greatest degree of gross arteriosclerosis and the greatest concentration of mucopolysaccharides (Fig. 1). Extracts of aorta from the male breeders exhibited less anti-coagulant effect and showed less mucopolysaccharide histologically.

Our findings are similar to those of Gore and Larky[7] in that we have found that the aorta contains an anti-coagulant in its wall. In addition, our results show that anti-coagulating activity is actually more pronounced in animals with arteriosclerotic aortæ. The prolonged clotting of blood found in these arteriosclerotic rats *in vivo* coincides with the demonstration of an anti-coagulating factor in the *in vitro* tests. The present consensus is that the normal aorta contains an anti-coagulant which maintains the normal fluidity of blood and prevents the formation of mural thrombi[4,5]. It has been suggested that during the development of atherosclerosis the nature of the mucopolysaccharides of aortic ground substance is altered resulting in the loss of this protective mechanism, that is, prevention of thrombus formation. Our experience with atherosclerotic rats indicates that the latter mechanism does not apply in this experimental situation. On the contrary, atherosclerotic breeder rats show increased anti-coagulating activity with increasing concentration of aortic mucopolysaccharides which is proportional to the degree of advancement of atherosclerosis.

MATERNAL BEHAVIOUR IN THE RABBIT: EFFECTS OF ENVIRONMENTAL VARIATION

By VICTOR H. DENENBERG, PROF. M. X. ZARROW, WILLIAM D. KALBERER and A. FAROOQ
Departments of Psychology and Biological Sciences, Purdue University, Lafayette, Indiana

MAMMALIAN reproduction, in its broadest essence, starts with mating behaviour and terminates when the young are weaned. Between these two events is a complex chain of genetic, biochemical, physiological, environmental and behavioural phenomena all of which are critical for the survival of the young[1]. Recent work has shown that disruption of this chain at different points can have deleterious effects on mammalian reproduction. Parkes and Bruce[2] have reviewed the evidence showing that implantation is blocked in the mouse if the female is exposed to the odour of a strange or alien male during the first four days of pregnancy. Eleftheriou *et al.*[3] have obtained the same results with the deermouse; in addition, they found that changes in the physical environment also resulted in a significant decrease in implantation. Calhoun[4] has reported that pregnant rats living under conditions of maximal population density frequently failed to carry their young to term; in addition, many of the litters which were successfully delivered died before weaning. In all these species, manipulation of dimensions of the external environment significantly affected reproductive physiology and maternal behaviour. The purpose of this article is to extend this generality to another species—the rabbit.

As part of a programme investigating determinants of maternal behaviour in the rabbit, a special experimental maternity cage was built. This cage permits quantification of various aspects of maternal behaviour including nest-building, number of entries into the nest-box, and general activity outside the nest-box. Dutch-belted female rabbits, born in the laboratory, were maintained in stock-room cages after weaning under uniform conditions until sexual maturity. They were then removed, mated and placed individually into standard colony cages or into the experimental maternity cages.

The standard colony cage consisted of a battery of four cages with an area approximately twice that of the stock-room cages. The cages were of wire construction and contained a nesting box 11 in. × 11 in. × 22 in. The experimental cages were made of wood with a wire top and bottom. These cages had an area approximately four times as great as the stock-room cages. A nesting box (10 in. × 7 in. deep × 20½ in.) was at one end of the cage. Figs. 1–3 illustrate the cages.

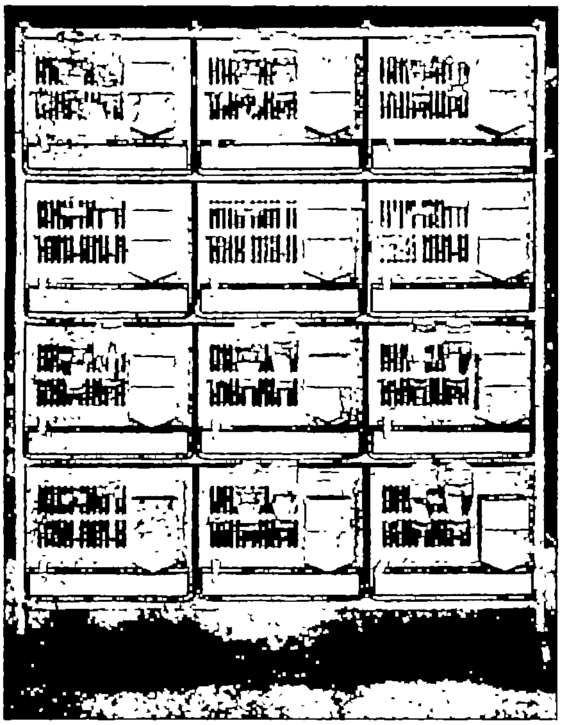

Fig. 1. Twelve-unit stock-room cage in which animals were housed from weaning to sexual maturity, when they were removed, mated and placed either in the four-unit standard colony cage (Fig. 2) or in the experimental maternity cage (Fig. 3). The respective sizes of the individual cages were 13·5 in. × 18 in. × 24 in.; 36 in. × 16 in. × 13·5 in.; 24·5 in. × 21·5 in. × 76·5 in.

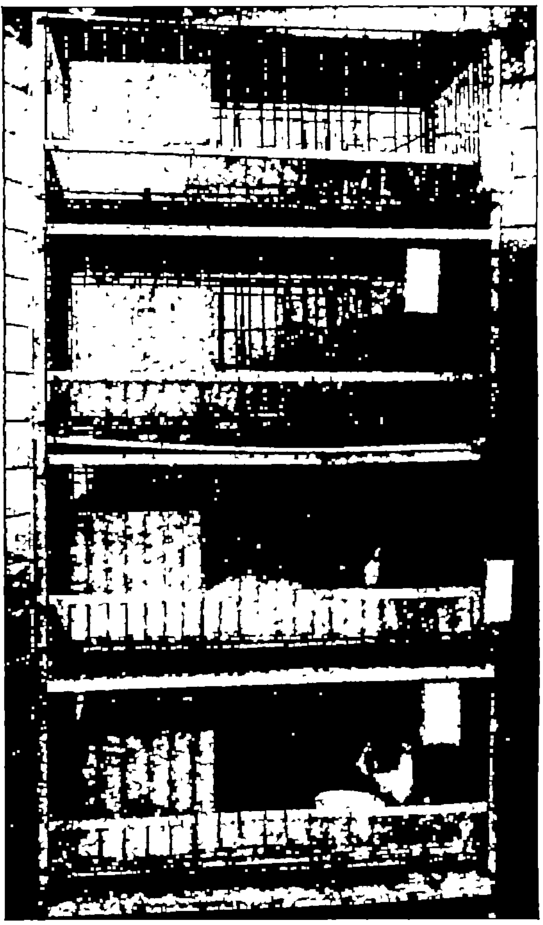

Fig. 2. Standard colony cage

Fig. 3. Experimental maternity cage

The control animals ($N = 100$) and experimental animals ($N = 27$) were provided with nesting material and nest-boxes as soon as they were placed into their respective cages. The controls were given access to straw for nesting material while the experimental rabbits were provided with 'Excelsior' (this was used as nesting material because it could be made into 'wads' which were easily counted). After being placed in the maternal environments the animals were minimally disturbed. All animals were kept under standard conditions of food and water (supplied *ad libitum*), light (13 h light per 24 h), and temperature (70°–72° F).

The following results were recorded: (1) Length of gestation; the day of mating was defined as day one of gestation. (2) Number of females building a maternal nest, that is, a nest of straw or 'Excelsior' into which the female had incorporated hair plucked from her body[5]. (3) Incidence of scattering, that is, the birth of one or more young outside the nest-box. (4) Incidence of cannibalism, that is, eating part or all of one or more young. (5) The percentage of young which survived through weaning.

Table 1 summarizes the findings. The mean length of gestation did not differ significantly between the two groups. All other differences are significant well beyond the 0·01 level as determined by χ^2 or exact probability tests. The rabbits which delivered in the experimental cages were deficient in maternal nest-building and exhibited a greater incidence of scattering and cannibalization. In addition, 87·3 per cent of the young born of control mothers survived until weaning but only 25·9 per cent of the young born to the experimental mothers survived.

Table 1. SUMMARY OF STATISTICS ON MATERNAL BEHAVIOUR IN THE RABBIT

Variable	Control ($N = 100$)	Experimental ($N = 27$)
$\bar{X}$ Length of gestation	31·8	31·8
Per cent built maternal nest	98·0	48·2
Per cent scattered young	6·0	66·7
Per cent cannibalized young	3·0	22·2
Per cent young surviving Through weaning	($N = 552$) 87·3	($N = 143$) 25·9

The experimental maternity cages are approximately four times as large as the stock-room cages and differ from the stock-room cages in terms of material, pattern, shape, amount of light admitted, etc. For example, the experimental maternity cages are much longer and made of wood, while the standard colony cage is smaller and much more comparable with the stock-room cages. This suggests that placing the animals into a markedly different environment after mating is enough to interfere with normal maternal behaviour. These results, in combination with other findings[2–4], strongly suggest that the external environment, rather than merely having a supportive role, has a dynamic effect in guiding the course of mammalian reproduction. There are other data suggesting that these effects may have long-term consequences for the species since manipulation of maternal factors have been shown to affect the offspring's behaviour[6–8]. Harlow's[9] findings are particularly pertinent here. He has shown that monkeys raised from birth by mother surrogates exhibit maladaptive mating behaviour and, in the few instances when pregnancies have occurred, defective maternal behaviour.

This investigation was supported in part by grants *BG*–5228 and 6263 from the Division of Research Grants, National Institutes of Health, U.S. Public Health Service. The work was carried out at Purdue University.

ACTIVATION PRODUCT AND THE FIBRINOLYTIC SYSTEM

By CHRISTINE HAWKEY

Department of Hæmatology, St. George's Hospital Medical School, London, S.W.1

ACTIVATION product was first prepared by Waaler[1] by the 'Celite' contact activation of factor XII (Hageman factor) and its subsequent interaction with factor XI (plasma thromboplastin antecedent). As prepared, it is free from significant contamination by other clotting factors: its addition to blood in a siliconed or plastic container leads to a considerable shortening of the clotting time. Interest in a possible connexion between the initial phase of *in vivo* clotting and the activation of fibrinolytic mechanisms led to an investigation of the fibrinolytic properties of activation product.

Activation product was prepared by the method of Waaler. Preparations were stored at − 30° C for up to 4 weeks before use. Techniques used for identification of components of the fibrinolytic system were the fibrin plate method[2,3] using both unheated and heated fibrin, and the standard clot method[4]. Plasminogen was activated by urokinase or streptokinase. Proactivator activity was estimated by the capacity of the test material to bring about lysis on an unheated bovine fibrin plate in the presence of streptokinase. Acceleration of clotting activity was assessed by the power of the activation product to shorten the recalcification time in a plastic tube of citrated plasma, collected and prepared without contact with an activating surface.

Activation product alone produced no lysis on unheated or heated fibrin plates (Table 1), and its incorporation in a standard clot prepared from human fibrinogen and bovine thrombin did not shorten the clot lysis time (Table 2). It was therefore concluded that activation product contains no free plasmin or plasminogen activator.

Activation product treated with urokinase or streptokinase, both potent activators of human plasminogen, failed to produce lysis on a heated fibrin plate (Table 1). This

Table 1. FIBRIN PLATE TESTS TO SHOW PRESENCE OR ABSENCE OF PLASMINOGEN, PLASMINOGEN ACTIVATORS AND 'PROACTIVATOR' IN ACTIVATION PRODUCT

Test mixture	Area of lysis in mm² Unheated plates	Area of lysis in mm² Heated plates

Table 2. STANDARD CLOT TESTS FOR PLASMINOGEN, PLASMINOGEN ACTIVATOR AND PLASMIN IN ACTIVATION PRODUCT

Test mixture (ml.)			Standard clot		
Activation product	Saline	SK 10 units/ml.	Fibrinogen* 500 mg/100 ml.	Thrombin† 5 units/ml.	Lysis time (min.)
—	0·7	0·1	0·2	0·1	60
0·7	—	0·1	0·2	0·1	25
0·7	0·1	—	0·2	0·1	68

* Human fibrinogen, Kabi, Stockholm.
† 'Bovine Thrombin Topical', Parke Davis and Co.

appeared to indicate that plasminogen was absent, but as the fibrin plate method is known to be insensitive to small degrees of fibrinolytic activity, this result was not accepted as conclusive. A more sensitive standard clot preparation, containing activation product and urokinase or streptokinase, lysed in a shorter time than a control clot (Table 2), indicating the presence of some plasminogen. This was confirmed by estimation of the esterase activity of the same mixture. (By courtesy of Dr. A. J. Johnson, New York University College of Medicine, New York.) Attempts to measure the amount of plasminogen in several preparations of activation product always indicated less than five units to be present, one unit in this instance being defined as the amount of plasminogen which, when activated, would form the amount of plasmin necessary to lyse a 1·1 ml. volume standard clot in 10 min. By this standard, normal human plasma contains 5,000–7,000 units of plasminogen per ml.[4].

Streptokinase (SK) alone will not activate bovine plasminogen[5], but if a small amount of human plasma or serum is mixed with the streptokinase, activation of bovine plasminogen is marked. This fact is explained by assuming that the human reagent provides a 'proactivator' which reacts with streptokinase to form plasminogen activator[6]. Proactivator has not been isolated and may or may not be part of the human plasminogen molecule[7]. It was found that the addition of activation product to streptokinase on an unheated bovine fibrin plate produced a considerable degree of lysis but, as has already been mentioned, lysis did not occur with the same mixture on a heated plate (Table 1). This finding is interpreted as indicating that activation product possesses proactivator activity. This proactivator activity is stable at room temperature and is still present in activation product diluted to 1 : 32. It is not destroyed by heating at 54° C for 4 h or at 80° C for 30 min. A trace of activity was found in samples which had been heated at 80° C for 4 h (Table 3).

Parallel experiments to measure clotting acceleration, proactivator activity and plasminogen activity in samples of activation product incubated at different temperatures, showed proactivator and plasminogen to be independent of the clotting activity of activation product. The latter was destroyed completely by heating at 54° C for 10 min (Table 4), while plasminogen and proactivator remained unaffected after 4 h at this temperature (Tables 3 and 5). This independence of clotting activity and fibrinolytic activity was confirmed by tests on activation product prepared from the plasma of patients deficient in factor XI or factor XII. The plasminogen and proactivator content of these preparations equalled that of activation product from different samples of normal plasma.

Table 3. PROACTIVATOR ACTIVITY OF ACTIVATION PRODUCT AFTER INCUBATION AT VARIOUS TEMPERATURES

Incubation time	Area of lysis in mm² after incubation at: 0° C	56° C	80° C
0	120	120	120
10 min	110	100	36
20 min	121	100	24
30 min	96	94	12
1 h	121	124	trace
2 h	120	110	trace
4 h	110	94	trace

Samples of activation product were incubated at temperatures shown. Sub-samples were taken at intervals, mixed with SK and tested on unheated bovine fibrin plates* as in Table 1.
* No lysis occurred on heated fibrin plates.

Table 4. THE CLOTTING ACCELERATION ACTIVITY OF ACTIVATION PRODUCT AFTER INCUBATION AT VARIOUS TEMPERATURES

Non-activated human plasma (ml.)	Type of tube	Added reagent (0·2 ml.)	Recalcification time (sec)
0·2	Plastic*	Saline	587
0·2	Glass	Saline	175
0·2	Plastic	Activation product	150
0·2	Plastic	Activation product after 4 h at 0° C	162
0·2	Plastic	Activation product after 10 min at 56° C	600
0·2	Plastic	Activation product after 10 min at 80° C	561

Samples of activation product were incubated at temperatures shown. The ability of sub-samples to shorten the recalcification time of unactivated plasma was tested at intervals.
* Polystyrene.

Table 5. PLASMINOGEN CONTENT OF ACTIVATION PRODUCT AFTER INCUBATION AT VARIOUS TEMPERATURES

Incubation time	Lysis time (min) after incubation at: 0°	56°	80°	Control (no activation product)
0	30	30	30	75
10 min	29	33	77	77
20 min	30	33	76	74
30 min	32	38	79	76
1 h	30	35	76	79
2 h	30	37	76	69
4 h	30	38	80	73

The lysis time of a standard clot preparation* containing activation product and SK.
* Standard clot preparation as for Table 2.

Plasminogen, measured by the standard clot method, was destroyed by heating at 80° C for 10 min, but proactivator activity remained measurable after 30 min at this temperature and a trace was still present even after 4 h. The fact that proactivator activity could be demonstrated in the absence of definable plasminogen may indicate proactivator to be a separate entity, or may merely reflect the insensitivity of the test for plasminogen.

The experiments described fail to provide information about possible links between the initiation of clotting and fibrinolysis *in vivo*. But it has been shown that activation product prepared from human plasma, although said to be free from contamination with other clotting proteins, does contain certain components of the fibrinolytic system. Free plasmin and plasminogen activator were not present, but small amounts of plasminogen were demonstrable and all batches prepared possessed proactivator activity to a considerable degree. This activity was independent of the ability of activation product to shorten the recalcification time of unactivated plasma. No clear-cut distinction between plasminogen and proactivator activity was obtained; slight variation in heat stability could be due to difference in sensitivity of the methods used.

I thank Dr. M. B. Howell for helpful discussions and I am grateful to Dr. J. L. Stafford for his advice. The investigation was supported by a grant from the St. George's Hospital Research Fund.

DURING the investigation of the family (Fig. 1) of a patient with sickle cell anæmia, a 'new' minor hæmoglobin component was encountered. This hitherto undetected hæmoglobin appeared to be a variant of hæmoglobin A_2. Since it was first observed in a subject from the Flatbush area of New York City, it has been tentatively designated hæmoglobin Flatbush (abbreviated to Hb. Flat.)[1]. This article deals with some of the characteristics of Hb. Flat., and with family studies which provided data concerning the linkage of Hb. Flat. with Hb. S.

Haemoglobin Flatbush. During electrophoresis at *p*H 8·8 on starch gels in borate buffer[2], Hb. Flat. migrated in approximately the same position as did Hb. S, and was estimated to account for 1 or 2 per cent of the total pigment (Fig. 2). Hb. Flat. was also detected on electrophoresis on starch granules at *p*H 8·6 (ref. 3), but a long period of electrophoresis (40 h) was required to achieve separations which were adequate for quantification. This new variant was not demonstrated by electrophoresis on agar gels at *p*H 6·2 (ref. 4), or on paper at *p*H 8·6. Preparations of Hb. Flat. purified by electrophoresis on starch granules exhibited slightly greater anodic mobility on starch-gel electrophoresis than did Hb. S; but we have thus far been unable to demonstrate directly the presence of Hb. Flat., in the presence of Hb. S. Hæmolysates containing Hb. Flat. did not contain increased amounts of alkali-resistant hæmoglobin, and a sample of Hb. Flat. eluted from an electrophoretic separation on starch granules had approximately the same resistance to denaturation by alkali as did Hb. A.

In each of 9 carriers of Hb. Flat., hæmoglobin A_2, the minor basic component described by Kunkel *et al.*[5] was notably decreased (Table 1). In these 9 subjects, Hb. A_2 values, ranging from 0·8 to 1·1 per cent, were approximately half the values obtained in normal subjects. In 8 family members whose hæmoglobin appeared entirely normal, hæmoglobin A_2 values of 1·8–3·2 per cent were within the normal range in our laboratory. The method of direct quantification of Hb. Flat. by elution after a 40-h electrophoretic separation on starch granules was established late in the investigation and was applied to only 3 hæmolysates. Even in these prolonged electrophoretic separations, it was at times difficult to separate Hb. Flat. completely from Hb. A. Hb. Flat. apparently accounted for 1–2 per cent of the total hæmoglobin in carriers who had Hb. A_2, Hb. Flat., and Hb. A. In 3 individuals with sickle cell trait (Fig. 1, II, 5; II, 8; and II, 16), Hb. Flat. could not be demonstrated directly, but its presence was inferred from the decreased amounts of Hb. A_2 observed on starch gels, and from the family studies.

Ceppellini *et al.*[6] described the first recognized variant of Hb. A_2, which is designated Hb. B_2. Hæmoglobin B_2 was readily detected and quantified since it migrated to the cathode on electrophoresis at *p*H 8·6. In Hb. B_2 carriers, Hb. A_2 and Hb. B_2 each accounted for about 1 per cent of the hæmoglobin. Thus the sum of Hb. A_2 and Hb. B_2 was approximately equal to the usual A_2 value of 2 per cent. Further evidence of allelism of Hbs. A_2 who noted the absence of Hb. A_2 in an individual whose and B_2 may be inferred from the studies of Horton *et al.*[7]. Hb. B_2 amounted to 2·1 per cent. Although this individual was probably homozygous for Hb. B_2, family studies could not be carried out. The results of fingerprinting studies of Hb. B_2 (ref. 6) have indicated that it differs from Hb. A_2 in a single peptide of the δ-chain.

A comparable situation was observed in the heterozygotes for Hb. Flat. While incomplete separation from Hb. A probably resulted in erroneously elevated values for Hb. Flat., the normal amount of Hb. A_2 was clearly reduced by about a half, and the sum of Hb. A_2 and Hb. Flat. was 2·5 per cent of the total pigment. Hæmoglobin A_2 is a tetramer of two kinds of polypeptide chains ($\alpha_2^A\delta_2^{A_2}$). Since the α-chain of hæmoglobin A_2 is apparently identical with the α-chain of hæmoglobin A ($\alpha_2^A\beta_2^A$), any alteration in the α-chain would be expected to result in another major hæmoglobin component as well as a second minor component. Only 3 hæmoglobins, A_2, Flat. and A,

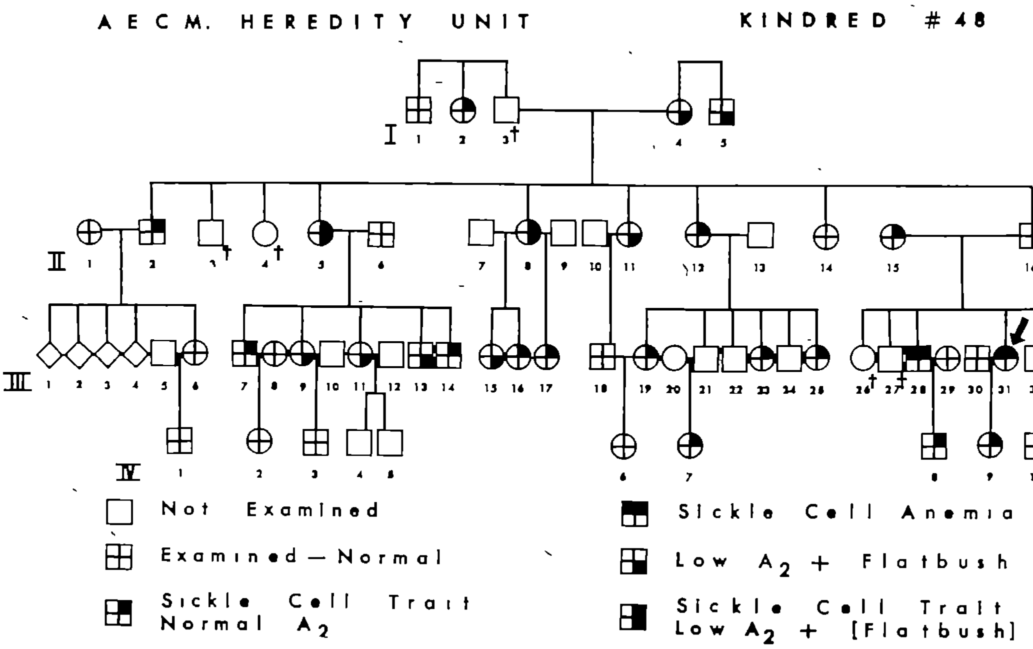

Fig. 1. Kindred segregating for hæmoglobin Flatbush and hæmoglobin S. No information is available concerning individuals represented by diamond symbol. *Subject IV, 11 was examined at 8 months of age: he had decreased Hb. A_2 and small amounts of a component with the mobility of Hb. Flat. However, since alkali-resistant hæmoglobin was present, final interpretation has not been made

were observed in Hb. Flat. carriers. The evidence therefore suggested that Hb. Flat. contained an alteration in the δ-chain, and its formula might consequently be written $\alpha_2^A\delta_2^{\text{Flat}}$.

Further evidence that Hb. Flat. contained an altered δ-chain was obtained by recombination experiments utilizing hæmoglobin $I_{\text{Burlington}}$ (ref. 7). As in the case of hæmoglobin A_2 (ref. 8), recombination was observed only after long periods of acidification of the mixture of hæmoglobin I and Hb. Flat. After acidification of a mixture of these hæmoglobins (as cyanmethæmoglobin) for 96 h, two new species of hæmoglobin of mobility intermediate between Hb. I and Hb. Flat. were observed:

$$\begin{array}{cccccccccccc}
\alpha_2^I\beta_2^A & + & \alpha_2^A\delta_2^{\text{Flat}} & \rightarrow & \alpha_2^I\beta_2^A & + & \alpha_2^I\delta_2^{\text{Flat}} & + & \alpha_2^A\beta_2^A & + & \alpha_2^A\delta_2^{\text{Flat}} \\
\text{Hb. I} & & \text{Hb. Flat.} & & \text{Hb. I.} & & \text{double abnormal Hb.} & & \text{Hb. A} & & \text{Hb. Flat.}
\end{array}$$

There were several differences between Hb. Flat. and the previously described minor components of approximately the same electrophoretic mobility. Hæmoglobin Lepore[9], hæmoglobin Pylos[10], and hæmoglobin 'G' (ref. 11), have about the same electrophoretic mobility as did Hb. Flat., but Hbs. Lepore, Pylos, and 'G' occurred in larger amounts (6–12 per cent). In the heterozygous state, these three previously described hæmoglobins have been associated with the hæmatological findings of thalassæmia minor. The simultaneous presence of Hb. Lepore (or Pylos) and high A_2 thalassæmia led to a marked interaction, resulting in an illness clinically resembling thalassæmia major[9,10]. In contrast, none of the individuals with Hb. Flat. had any hæmatological abnormalities and the simultaneous presence of Hb. Flat. and Hb. S did not result in any evident interaction. Currently available evidence concerning the structure of Hb. Lepore is conflicting[12,13], suggesting that Hbs. Lepore from different sources may have differences in structure.

Family studies. The family (Fig. 1) in which Hb. Flat. was detected was of Puerto Rican ancestry. Blood groups, including ABO, MN, Rh and Kell, were determined on all available members of the family. No evidence for non-paternity was found.

In generation I, the mother (I, 4) and her brother (I, 5) were Hb. Flat. carriers. In generation II, four hæmoglobin phenotypes were detected: AA – A_2A_2, AA – Flat. A_2, AS – A_2A_2, AS – Flat. A_2. The assumption that the father (I, 3), who was dead, must therefore have had sickle-cell trait was strengthened by the finding of sickle-cell trait in his sister (I, 2). In generation II, three individuals (II, 5; II, 8; II, 16) had decreased Hb. A_2 and sickle-cell trait. As noted here, the presence of Hb. Flat. was inferred from the decreased levels of Hb. A_2. These three individuals had 12 children; 7 of the children inherited the Hb. S and the remaining 5 the Hb. Flat. from the doubly heterozygous parent. (The genetic contribution of the father (II, 16) to his children (III, 28; III, 31; III, 33) was clearly defined even though the mother (II, 15) had sickle-cell trait; two of the children inherited Hb. S from each parent and had normal levels of Hb. A_2, the third child had the hæmoglobin phenotype AA – Flat. A_2.) None of these 12 children in generation III had entirely normal hæmoglobin or Hb. S with decreased A_2. The results from the first three generations indicated that, in this kindred, the β-chain locus responsible

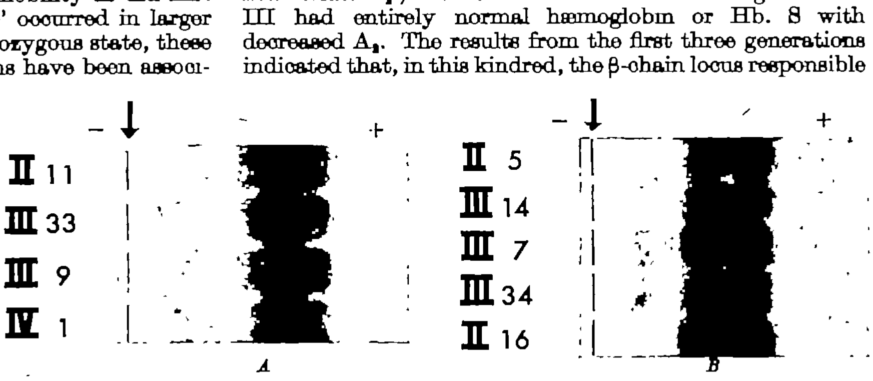

Fig. 2. Benzidine stained vertical starch-gel electrophoretic analyses (ref. 2) in borate buffer pH 8·8 of hæmoglobin (concentration 3 g/100 ml.)

A, components (cathode to anode): hæmoglobins A_2, Flat., A. In hæmolysate of II, 11, III, 33, and III, 9, the presence of Hb. Flat. and decreased Hb. A_2 was noted. Hæmoglobin of IV, 1 appeared normal

B, components (cathode to anode): hæmoglobins A_2, S and A. In hæmolysates of II, 5 and II, 16, Hb. A_2 was decreased, but Hb. Flat. was not detected in the presence of Hb. S. The hæmoglobin patterns of III, 14, III, 7, and III, 34 indicated sickle cell trait with normal Hb. A_2

for the synthesis of Hb. S, and the δ-chain locus responsible for the synthesis of Hb. Flat. were in the repulsion phase in the three doubly heterozygous individuals in generation II. The hæmoglobin phenotypes of the 12 critical offspring in generation III are consistent with linkage of the β- and δ-polypeptide chain genetic loci.

Evidence for the linkage of the δ-chain locus with high A_2 thalassæmia was provided in the kindred studied by Huisman *et al.*[14], in which these two loci appeared to be in the coupling phase in 3 individuals with thalassæmia minor and Hb. B_2. Of the 14 children of the doubly heterozygous individuals in their study, 11 had both Hb. B_2 and thalassæmia and 3 were normal. Since the loci for high A_2 thalassæmia and for the β-polypeptide chains appear to be linked[15], the family studied by Huisman *et al.*[14] provides evidence for linkage of the δ- and β-chain loci. Direct evidence concerning δ–β-linkage had been obtained earlier by Ceppellini[5], who studied one family in which the father was heterozygous for both Hb. S and Hb. B_2 and the mother had normal hæmoglobin. Of their 6 children, 4 had sickle cell trait and the others had hæmoglobin B_2. The family studied by Horton *et al.*[6] yielded less information concerning linkage of the β- and δ-loci: while the father was doubly heterozygous for hæmoglobins B_2 and S, the mother also had Hb. B_2.

The homozygous state for Hb. Flat., in which hæmoglobin A_2 would be expected to be completely absent, has not been encountered. Such a finding would provide definite evidence concerning the allelic relationship of Hb. Flat. and Hb. A_2. However, when the evidence provided by the present kindred with Hb. Flat. is considered together with the accumulated data on Hb. B_2, it seems very likely that Hb. Flat. represents another allele of Hb. A_2 with an alteration of the δ-polypeptide chain.

The family studied by Ceppellini[5] and the present kindred together include eighteen offspring of individuals who were heterozygous for both β- and δ-polypeptide chain variants. The two hæmoglobin phenotypes which are consistent with linkage of the β- and δ-chain genetic loci were observed in all of the eighteen children. The other two possible phenotypes were not encountered. Statistical analysis of these results ($P = < 0·005$ from χ^2 test) appears to establish linkage of the genetic loci responsible for β- and δ-polypeptide chain synthesis.

This work was supported by a grant (contract *U*–1039) from the Health Research Council of New York City and by grant *A*–4502 from the National Institute of Arthritis and Metabolic Diseases, U.S. Public Health Service.

We thank Dr. R. Gross, who assisted in obtaining blood samples from the members of the family in Puerto Rico.

STATISTICAL VARIATION FOUND AT POCK AND PLAQUE COUNTING OF VACCINIA VIRUS

By DR. K. MAI

Institut für klinische Bakteriologie und Serologie der Universität

AND

DR. K. BONITZ*

Zentrallaboratorium des Allgem. Krankenhauses Eilbek, Hamburg

IN *Nature* of March 31, 1962[1], the opinion of some authors is quoted according to which the count variance in the method of counting pocks in the chick chorio-allantois is so great that no valid estimate of the over-all coefficient of variation is possible. The quotation, although verbatim for the rest, is incomplete, lacking the supplement "—though others disagree—" used in the original text[2] as a qualification to these authors mentioned but not named.

The conclusions drawn in the review are strongly biased in favour of indirect particle counting, represented above all by the rabbit scarification method with the improvements given by Kolb *et al.*[3], but still based on measuring the percentage area covered either by confluent eruptions or individual lesions. The doubtfulness of adding up confluent reactive areas, which may conceal uncontrollable lots of infective units, together with single pocks is obvious. This fundamental disadvantage is similarly common to all titration devices establishing relations between dilutions and percentage effects; it may, however, be moderated by correct statistical handling as usual with the so-called ID_{50} methods. Compared with direct counting all indirect methods are highly debited with loss of information and, therefore, not economic, as Cooper[4] has recently pointed out on the occasion of discussing the relationship of plaque-forming units to end-point dilution units.

For these reasons as well as with regard to our own experience with direct pock and plaque counting of vaccinia virus we should like to join those "others disagreeing". Investigations with chorioallantoic membrane pock counting[5–9], cited by Kolb[3] as a warning, failed to explain the high count variance inherent to this technique. We feel that this may be due, at least partially, to the fact that most workers in the field of pock counting neglected to use Fisher's index of dispersion for small samples from a Poisson distribution, first inaugurated by him in connexion with plating counts of soil bacteria[10] and afterwards conveyed into his famous text-book[11]. The only exception seems to be the study of Reid *et al.*[12] on fowl pox virus titration which, favoured by the additional circumstance of low sample means, fulfilled the conditions of Poisson expectation. The habit of estimating the counting accuracy by comparing the counts of several dilutions made from the same suspension, adopted in the early stages of the method[13] and thoroughly preserved, may be of great secondary help but cannot

---

* Formerly: Leiter des Laboratoriums der Impfanstalt Hamburg.

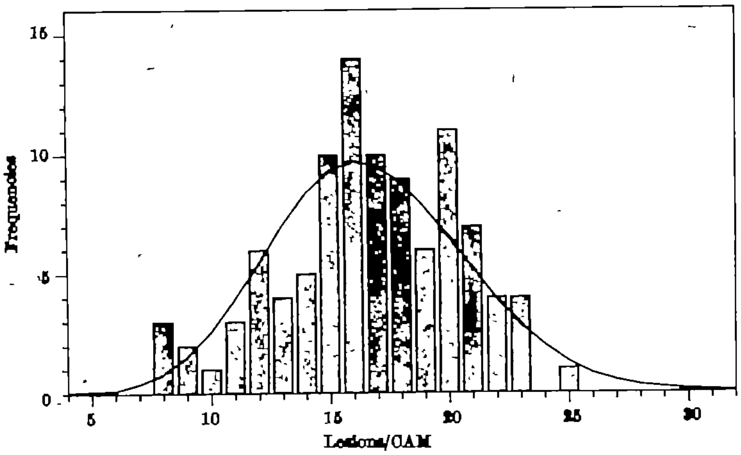

Fig. 1. Distribution of pock counts on 100 chorioallantoic membranes (CAM) inoculated with a 10^{-3} diluted suspension of vaccinia virus (lot 8/2 from bovine embryonic muscle t. c.). The line connecting frequencies of the Poisson series pertinent to the sample mean of 16·71 (± 0·41) designates expectation. Goodness of fit is ascertained by a χ^2 of 10·26 (12 d.f.) resulting in a probability higher than 0·6, which is exceptional for chorioallantoic membrane samples even of this size

replace examinations of the variance in the counts gained of one single dilution.

The index of dispersion is calculated by dividing the sum of squared deviates from the sample mean by the mean itself (1). Thus a sum of squared normal deviates is obtained, generally known as a χ^2, provided that the variance of the underlying distribution be

$$\chi^2 = \frac{\Sigma(x - \bar{x})^2}{\bar{x}} \qquad (1)$$

numerically equal to the mean, which is in fact one of the criteria natural to the Poisson distribution, here the hypothesis under test. Note (2) that the index of dispersion, replacing the sampling variance v for subsequent considerations, is proportional to this statistic (the sum

$$\chi^2 = \frac{(n - 1).v}{\bar{x}} \qquad (2)$$

of squares divided by the number of degrees of freedom) since the mean $\bar{x}$ and the number n of observations in the sample can be regarded as constants for the actual case. For the use of these formulæ in the way of approximating the Poisson distribution to a normal one with its variance equal to the mean, a condition as to the order of magnitude has to be satisfied, the product $n\bar{x}$ being supposed to be larger than about 30, which is the case with our data as it certainly will be in similar investigations.

In the experiments leading to this article the chorioallantoic membrane pock-forming units were counted by the method of Westwood *et al.*[9], slightly modified; for counting plaque-forming units a tissue culture of bovine embryonic muscle with hæmadsorption plaque reading[14] was used.

Having obtained (Fig. 1) sufficient support for the actual occurrence of the presumed distribution type from experiments with enlarged samples (100 embryonated eggs or 200 tissue culture tubes respectively, inoculated with one virus suspension at a time) we applied the χ^2 index to samples of routine size (5–8 chorioallantoic membranes, 5–10 tissue culture tubes). The lot of values gained by computing each sum of squares following one of the usual formulæ and dividing it by the corresponding mean turned out to be useful in several ways:

(1) Each sample under consideration can be tested for homogeneity by referring to the 1 or 5 per cent significance points of a tabulated χ^2 distribution; in cases of significant departure from the Poisson hypothesis the mean cannot be regarded as reliable, so the counting may have to be repeated, the reason for the development of a variation greater than explicable by chance should be found out, etc. Modifications of the established significance levels are practicable in special cases which will be referred to.

(2) A more comprehensive evaluation of the indexes is at hand if χ^2's and proper degrees of freedom are added up. Samples of different size can thus be put under test together, and arrangements following certain technical characteristics of the samples, for example, the dimensions of means, will supply particulars about experimental deficiencies.

(3) Arraying the indexes into a frequency distribution for comparison with the theoretical expectation leads to a most sensitive and versatile test. Classes are readily deduced from the probability divisions of a χ^2 table, their number and ranges depending on the number of indexes to be filed up. Departure of the observed distribution in the direction of high probabilities designates a degree of particle dispersion better than predictable by chance alone, while the other direction stands for an over-all variation greater than expected, if not for influences depressing the sample means, for example, overcrowding. For measuring the extent to which the variance is affected by such a shift of distribution (in order to rectify *S.E.* by an allowance fitted to the actual discrepancy between the ideally and partially fulfilled Poisson conditions) Fisher's own example may be followed, set up in connexion with the first display of the dispersion index under similar experimental circumstances[10]: if a distribution of indexes deviates significantly from expectation, a factor is easily determined indicating the amount of change in the variance by means of modifying the χ^2's of the distribution class limits so as to fit the actually found frequencies.

Parts taken from experimental data that will be published elsewhere in full detail[15] are given in Tables 1–4 as an illustration of the statistical treatments briefly enumerated here. Over-all variances differing widely between the two counting methods in question appear to be the most striking result, following from adding the sample indexes just as well as from the comparison of their distributions (Tables 1 and 3). The chorioallantoic membrane data so far demonstrated are all derived from counts of tissue culture vaccines; the findings are, however, quite the same with equally treated calf lymphs. Since further technical circumstances (sample size, suspension diluting procedure, etc.) also turned out to be of no fundamental influence, the overcrowding of pocks, already accused or at least taken under suspicion of seriously interfering with the chorioallantoic membrane titration[5–7], had again to be considered; it is, in fact, responsible to a remarkable extent for the high pock counting variability, as is shown by the d values in Table 2 increasing with the sample means. (The concomitant rise of the sample numbers per class is, of course, incidental, as provable by adding, for example, the samples of the second and third row to obtain from the resulting 26 indexes a d value of 2·92 which exactly fits the column ranking.) The rise of single pocks out of more than one infective unit each, depressing the mean and thereby increasing the χ^2 index, is altogether not surprising if the invariable smallness of the receptive area is kept in mind; this area is sometimes not even fully utilized, concluded from local accumulations and sparsenesses of chorioallantoic membrane lesions occasionally observed in spite of meticulous care taken with the inoculation, whereas the area available for tissue culture counting depends entirely on the experimenter's choice and is free to observation through the proceedings. No support for any overcrowding effect on plaque counts is obtained if tissue culture data are arranged in the way of Table 2; the d values, most

Table 1. ADDITION OF χ^2'S. COMPARISON OF POCK AND PLAQUE COUNTING METHODS

of them negative in sign, do not show any tendency whatever.

The slight but already significant tendency of the indexes derived from tissue culture samples towards a probability higher than predicted, meaning better particle dispersion than chance alone would yield, might be explained by mutual repulsion of the particles during sedimentation; if the presence of the tissue culture fluid were really responsible for bringing about this scatter effect, it would intimate an additional technical advantage over the chorioallantoic membrane from which small volumes of liquid are almost instantaneously resorbed. At last, the fact may be recalled that embryonated eggs will always represent a whole population of hosts, subject to biological variation in many respects; so the assumption of a variable susceptibility to virus infection in comparison with the homogeneous tissue culture seems to be reasonable.

The chorioallantoic membrane remains, however, a valuable counting recipient, easy at hand and inexpensive, therefore not even dispensable for those laboratories familiar with tissue culture work. So we are glad to have found a way of expressing the increase of the variance in case the Poisson variability is not fully achieved. Table 4 shows χ^2 table values modified by multiplication as to fit a distribution derived from 100 samples of 6 chorioallantoic membranes; the allowance of 60 per cent designated by the factor adjusted to 1·6 supplies a measure applicable to the over-all variance of the group. If one of these 100 samples has produced a mean of, say, 24 pocks, its *S.E.* can now be stated as being ± 2·53 instead of ± 2, the latter calculated assuming unrestricted Poisson conditions (variance equal to mean, *S.E.* expressed by the square root from the ratio of variance to number of counts). The example illustrates the fact that the *S.E.* for each sample in this group has to be raised by about 25 per cent (strictly 26·5 per cent, the square root of 1·6 being 1·265). The greatest necessary allowance for the variance in a group of samples amounted to 80 per cent; thus a raise of the *S.E.* by a third will include the highest possible risk of additional variation involved with the chorioallantoic membrane technique.

Table 4. FREQUENCY DISTRIBUTION OF χ^2 ARRANGED IN QUINTILES AND MODIFIED BY AN ALLOWANCE OF 60 PER CENT FOR THE VARIANCE

Precautions for practical work can be deduced from the foregoing. Significance limits for evaluating individual sample indexes properly modified and samples of still significant variability eliminated, the standard error of the means will not exceed 15 per cent (or 20 per cent as an extreme). Analogous calculations are practicable with confidence limits, significance testing for differences of sample means, etc., all based on the adjusted variances. The bearing of this for more differentiated laboratory work with vaccinia virus, for example, neutralization testing of sera, need not be emphasized.

The general conclusion from these findings points clearly to the validity of the Poisson distribution for pock as well as plaque counting of vaccinia virus. Restrictions as to the variability of chorioallantoic membrane pock counts can be explained by technical circumstances and compensated statistically to uphold the reliability of sample means. This ought to dispel doubts about the suitability of an efficient and economic method.

ASTRONOMY

A Typical Leonid Meteor Spectrum

CONSIDERABLE efforts have been made by many workers[1] to obtain meteor spectra. From the earlier observations it has been established that all meteor spectra from each shower are remarkably similar to each other, having the same general features within the limitations of photographic resolution and emulsion sensitivity[2].

This communication describes the first spectrum taken from India, at Waltair. The meteor appeared at 2 h 47 min I.S.T. on the night of November 15–16, 1961. Its visual magnitude has been estimated as brighter than – 2. It appeared green and had a terminal burst at which the wake remained visible for more than a minute. From the plot of its path on a star map it was found to proceed from the Leonid radiant. The spectrum of this meteor has been photographed on an Ilford *HP*3 film (*ASA* No. 400) using a conventional meteor spectrograph with the rotating shutter arrangement. The Agfa 35 mm camera used for this purpose carried before its $f/2$ lens a Bausch and Lomb plane replica transmission grating, with 200 lines per mm and blazed for 5000 Å. From the durations of the segments produced by the rotating shutter, the velocity of the meteor has roughly been estimated at 71 km/sec, which is in close agreement with the mean velocity for the Leonid shower.

The spectrum of the meteor is reproduced in Fig. 1. Five segments of the trail could easily be identified in the photograph. The brightness of the trail has gradually increased from the first to the last segment. The sudden increase in the brightness of the last segment corresponds to the terminal flare. The maximum intensity is found to occur in the yellow region in the first three segments, whereas it has shifted to the violet in the last segment, showing an increased excitation towards the end of the trail. This feature has already been noticed by Millman[2]. A weak secondary spectrum having a few lines has been recorded in the gap between the first and second segments. This is supposed to be produced by the material which broke off from the main mass and trailed behind it[3]. The spectrum of the persistent train has also been recorded in between the 4th and 5th segments. The analysis of this wake spectrum will be presented in another communication.

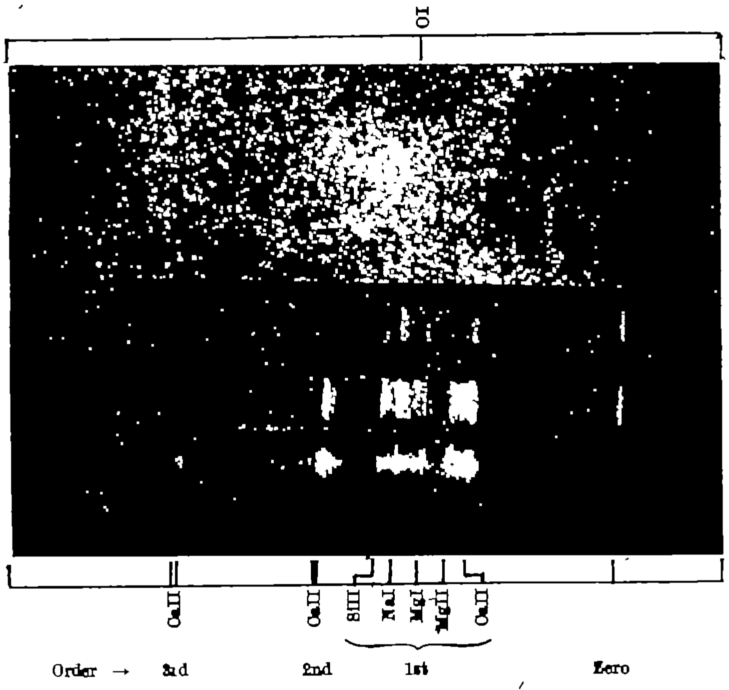

Fig. 1. Spectrum of the Leonid meteor observed at 02h 47m on the night of November 15–16, 1961. (As the secondary spectrum HI (1) and NI (20) lines are very faint, they have not clearly shown up in the reproduction. However, they could easily be identified in the negative)

Seven lines have been measured in the secondary spectrum, and their wave-lengths are presented in Table 1 along with their identifications. Five of them are found in the secondary spectrum of the Perseid meteor obtained by Millman[3]. A continuous line extending from above the first to the third segments has been identified as the oxygen green line. This line has been observed in 17 meteor spectra taken earlier[4] out of which only one corresponds to a Leonid meteor, and most of the others also correspond to high-velocity meteors. The present observation is consistent with the general feature that the oxygen green line occurs at heights greater than that of the maximum light in the meteor spectrum. The HI (1) (6568·1 Å) and the NI (20) (6656·3 Å) lines have also been identified in the first segment. The presence of the hydrogen, nitrogen and oxygen gases seems to lend support to Whipple's comet model[5], and also to Kuiper's suggestion that the water of crystallization of certain compounds may possibly be present in cometary meteoroids[6].

About 35 lines have been measured in the primary spectrum, which is clearly resolved in the fourth and fifth segments. The various possible multiplets, identified in this spectrum, are listed in Table 2. There the multiplet numbers correspond to those used in Dr. C. E. Moore's multiplet table[7]. These multiplets have all been identified in Perseid meteor spectra[3,4]. All the multiplets observed in the Leonid meteor spectrum of Millman[4] have been found in the present list excepting FeI (38).

Eight Leonid meteor spectra obtained by Millman[3] have been classified under type *Y* spectra, having the H and K lines of ionized calcium as the most prominent feature. The present spectrum also exhibits the same feature, confirming that the Leonid group is composed mainly of stone meteors. The presence of the strong lines of CaII, MgII and SiII in this spectrum supports Millman's suggestion[8] that the excitation may depend on the geocentric velocity.

RADIO ASTRONOMY

Radio-Transit Telescopes steerable in Azimuth

WHEN considering radio-transit telescopes, one ordinarily speaks in terms of instruments steerable in altitude. However, transit telescopes steered in azimuth have potentialities which should be evaluated. Bracewell[1] and Drake[2] have made suggestions for azimuth steerability. Both their designs utilize offset foci and the concept of a segmented reflecting surface.

The instrument proposed here would comprise a paraboloidal dish with fixed altitude supported by an infrastructure that is free to move in azimuth. Railway tracks may provide the azimuth mount; the 250-ft. Mark I reflector at Jodrell Bank is an example of this design[3]. The rotation of the whole structure through the desired angle accomplishes the steering. The structure behaves like a transit instrument for all sources at the declination which corresponds to the fixed altitude and adjustable azimuth. As usual with transit instruments, no guiding or scanning is possible.

The disadvantage of the instrument, compared with the altitude-steerable transit types which are designed to give horizon to horizon coverage, is that only a limited band of the celestial sphere between two declinations is accessible to observations. The altitude of the paraboloid determines the width of the band, and in general any source that lies within this band can be observed twice every 24 sidereal hours. To achieve complete sky coverage a number of such transit instruments at varying geographical latitudes would have to be erected, the number being determined by the altitude. If the altitude is too small, observations will be made too near the horizon and the height of the instrument may be too great if the diameter is large. If, on the other hand, the altitude is too great, there will be small sky coverage which will necessitate a larger number of instruments. Thus, for example, two azimuth-steerable transit telescopes each with an altitude $\alpha = 45° + \varepsilon$ ($\varepsilon \sim 1°$), with a diameter of D ft. and a maximum height $h \sim D \cos \alpha$ ft. situated at geographical latitudes 45° N. and S., would give complete sky coverage plus overlap at the equator with a half-power beam width of 112 λ/D min of arc at wave-length λ cm.

The number-diameter-altitude-cost-capability relationship of such a design could well be evaluated because of the following desirable features. (1) Greater resolution is achieved by spreading a greater projected surface area of the dish over a larger ground area. The rigidity of the Earth is therefore used to advantage. (2) The elimination of the degree of freedom in altitude simplifies construction problems. (3) The angle between the direction of gravity and any element both of the reflecting surface and the focus mounts will be the same for all positions of the telescope, and thus the structural members will not be subjected to varying loads during steering. (4) The instrument can be designed with a focus tower built directly upon the ground. This possibility would free the reflecting surface and its supporting infra-structure from the static loads that would occur if the feed were supported conventionally by a tripod mount, and greater accuracy of the reflecting surface might therefore be possible. In this case the structure must be designed to rotate about an axis coincident with the focus tower and on circular tracks with the base of the focus tower at centre.

GEOPHYSICS

Susceptibility Anisotropy Measurements on some Silurian Siltstones

ANISOTROPY of magnetic susceptibility, in certain sediments, is probably due to the preferred orientation of elongated magnetic grains. Rees[1] has shown that for varved silt redeposited in the laboratory the direction of the axis of maximum susceptibility is controlled initially by the geomagnetic field and in the final stages of deposition by water current and 'compaction' effects analogous to those which have been shown to affect the direction of remanent magnetization. This work reported here was undertaken to determine whether natural sediments also have an anisotropy which can be related to the direction of palæocurrent flow indicated by geological observations.

Orientated samples were collected from siltstone beds in the Kerry, south-west Clun Forest and Bishop's Castle areas of the Welsh borderland. The siltstone beds are of Lower Ludlovian age, and it has been suggested by Cummins[2] that they were deposited by turbidity current flows. Evidence of the direction of these currents is provided, at many sites, by sedimentary structures and other forms of lineation occurring at the base of, and within, the siltstone beds. Fourteen samples were collected from such sites, and 45 orientated cylindrical specimens have been obtained from these by coring.

The siltstones have a median diameter of 30–60 μm and are composed of between 30 and 40 per cent of clastic quartz in a matrix of finely divided sericite and/or calcite. Opaque minerals including magnetite form about 5 per cent of the rock.

For each specimen the directions of the principal axes of susceptibility were determined using a simple torsion magnetometer[3]. These directions have been plotted on a stereographic net. The maximum and intermediate axes of susceptibility lie nearly in the bedding plane, the minimum axes thus being perpendicular to it. A mean direction of the maximum susceptibility axis was estimated for each sample, from measurements on 3 or more specimens. These mean directions were plotted (Fig. 1) with respect to magnetic north, and were seen to have a considerable scatter. As an alternative, the mean directions were plotted with respect to the known current directions, determined from macroscopic indications, for the individual sampling sites (Fig. 2) and this considerably reduced the scatter. The directions of the mean maximum susceptibility axes appear to be aligned in the current direction and dip into this direction at an angle of about 10°.

Forces acting at the time of deposition control the orientation of the grains. On touch-down on the bed the grains tend to take up a position so as to offer least resistance to the flow. Rusnak[4] showed, from studies on sand

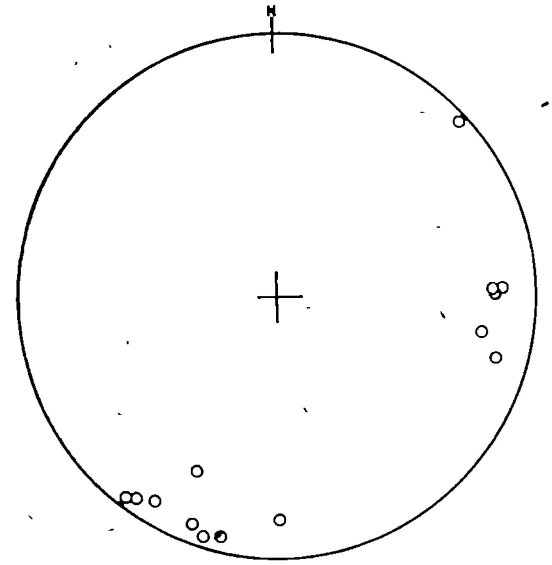

Fig. 1. Mean maximum susceptibility axes plotted with respect to magnetic North. All points lower hemisphere

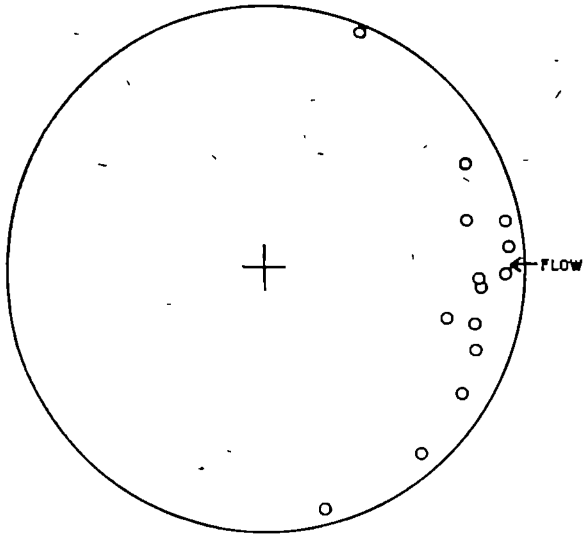

Fig. 2. Mean maximum susceptibility axes plotted with respect to known current direction. All points lower hemisphere

grains, that this is achieved when the grains are lying with their axes of elongation in the direction of flow. However, the magnetic field acting at the time of deposition might also be expected to produce some preferred orientation of the grains, but it is thought that the deposition of the siltstones occurred under high fluid stress conditions, where the effect of the magnetic forces in producing grain alignment was negligible compared with the effect of the hydrodynamic forces. Thus the present observations agree with Rusnak's findings. Furthermore, the dip of the axes into the upcurrent direction is of the same order as that described by Rusnak for sand of 100 µm diameter.

These results suggest that measurements of the directions of the axes of maximum susceptibility of rocks of the type described may, in certain cases, prove a reliable method for estimating current directions and be a valuable supplement to other palaeocurrent data. Earlier studies of grain orientation in fine-grained sediments, for example those of Dapples and Rominger[5], and Curray[6], have involved measurement of the projections of the grains in two dimensions. The present method enables the magnetic grain orientation to be determined in three dimensions and thus gives a clearer indication of the magnetic fabric of the sediment, which for these siltstones is thought to be the same as that exhibited by the non-magnetic grains.

The collection of the siltstone samples was made possible by the guidance in the field of R. J. Bailey, and I am indebted to him for permission to draw on unpublished data concerning the current directions in the area. I also thank the Department of Scientific and Industrial Research for providing a maintenance grant.

GEOLOGY

Multiple Solid Solution on Sulphides in Sphalerite

The mineral sphalerite is well known as a ready solvent, at elevated temperatures, for a number of other sulphides. On cooling, such a homogeneous solid solution unmixes, producing exsolution bodies of the solute aligned, ideally, along the structure planes of the sphalerite host.

Experimental work has established certain maximum solubilities while chemical analyses of minerals indicate varying degrees of solid solution under natural conditions. Sphalerite from St. Agnes, Cornwall, for example, contains as much as 26·2 per cent iron[1]. A number of solid solutions with sphalerite as solvent are known or are inferred from unmixing textures. The most common solutes are chalcopyrite, pyrrhotite and tetrahedrite. Others have been recorded but are rare. Unmixing textures involving more than one sulphide exsolved from a given sphalerite host are occasionally observed, for example, chalcopyrite and pyrrhotite sometimes with additional exsolved cubanite and/or valleriite.

A recent mineragraphic study[2] of a suite of polished sections from a small deposit of silver-rich mixed sulphide ore from Rockvale, near Armidale, New South Wales, has revealed a hitherto unexpected diversity of minerals exsolved from solid solution in sphalerite. The trends of unmixing are shown in Fig. 1.

The Rockvale ore is extremely complex with twenty-five different minerals in intimate intergrowth. The principal constituents are arsenopyrite, galena, argentian tetrahedrite, sphalerite, chalcopyrite, stannite, pyrite and composite grains of several ruby–silver minerals with

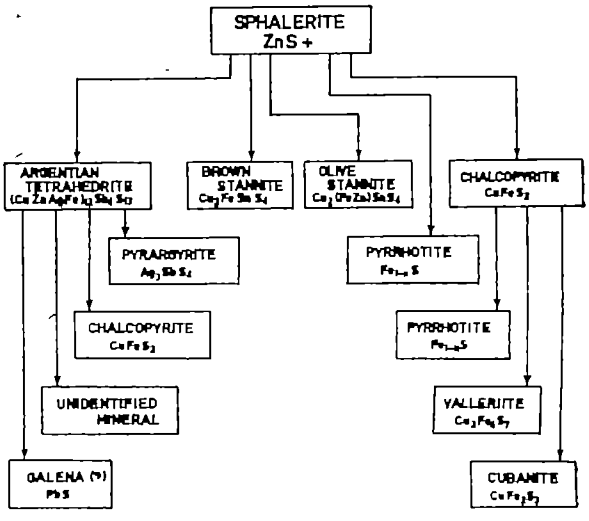

Fig. 1. Trends in the multiple unmixing of a solid solution of eight mineral phases of sphalerite

pyrargyrite predominating. Other constituents are accessory. Each of the principal constituents was deposited directly from the ore fluids and some of them also figure in exsolution processes in sphalerite. A number of them, in addition to sphalerite, also contain exsolution products. These include galenobismutite and traces of pyrargyrite in the (100) planes of galena, sphalerite in the basal planes of stannite, chalcopyrite and an unidentified grey-white mineral as interstitially exsolved solutes in argentian tetrahedrite.

The first mineral to unmix from solid solution in the Rockvale sphalerite was argentian tetrahedrite, which occurs as small rods in the (100) and the (111) planes of the host. A second-stage unmixing (Ramdohr's "*unterentmischen*") of the exsolved tetrahedrite yielded extremely minute wisps of chalcopyrite, the unknown grey-white mineral and small amounts of pyrargyrite. The possible exsolution status of occasional lamellæ of galena, orientated in the structure planes of the sphalerite and sometimes co-linear with tetrahedrite lamellæ, is questionable.

Further unmixing from the sphalerite produced lace-like aggregates of two varieties of stannite—an olive-coloured stannite and a brown stannite. These may correspond to zinc-rich and zinc-poor stannites, respectively.

Minute lamellæ of pyrrhotite precipitated in the (111) planes of the sphalerite occur in places.

Vigorous diffusion during unmixing of chalcopyrite is evident with the development of sphenoidal crystals aligned in the (111) directions of the sphalerite. Some of these exsolved crystals are monomineralic; the majority, however, have also undergone second-stage unmixing yielding, within the chalcopyrite, irregular areas and (111) precipitations of pyrrhotite exhibiting widmanstetten-like texture. Other chalcopyrite crystals show either cubanite and/or valleriite precipitated in the (111) planes of the chalcopyrite.

This unique unmixing of an initially homogeneous sphalerite has yielded no fewer than eight distinct mineral phases one of which (stannite) consists of two variations. So profuse was the unmixing that single grains of sphalerite only 0·5 mm diameter contain up to six or seven of these exsolved phases.

Omitting galena, the crystal structure of which would inhibit solid solution in sphalerite but which nevertheless has an exsolution appearance, an extended sphalerite composition (Zn, Fe, Cu, Sn, Sb, Ag)S is manifest for the homogeneous material prior to unmixing. The five non-essential metals (as sulphides) were assessed at some 10–15 per cent of the total.

METEOROLOGY

A Lunar Influence on Ice Nucleus Concentrations

RECENT papers by Bradley, Woodbury and Brier[1] and by Adderley and Bowen[2] have shown a remarkable relation between the phase of the Moon and precipitation.

The former showed that using the dates of heavy precipitation for each month recorded at the 1,544 United States weather stations which have operated continuously during the period 1900–49, there was a marked tendency for extreme precipitation near the middle of the first and third weeks of the lunar synodic month. The second paper showed a very similar result for the rainfall at 50 New Zealand stations in the same period, and the authors suggested that the Moon might perhaps modulate the amount of meteor dust collected by the Earth.

If this were so, and Bowen's theory that meteor dust reaches the lower atmosphere about 30 days after its arrival in the upper atmosphere were correct, then the ice nucleus concentrations at the ground should show corresponding maxima. It is scarcely conceivable that nuclei of local or terrestrial origin would be influenced by the Moon to a significant degree.

For several years ice nucleus concentrations have been measured in Australia, New Zealand and South Africa[3,4] during the summer months. These data have now been examined for a lunar effect in the following way: adopting Bradley, Woodbury and Brier's convention, the angular difference on apparent longitudes of the Sun and Moon at Greenwich noon was expressed as hundredths of the synodic month of 29·53 days, new Moon being 0·00 and full Moon 0·50. The temperature at which most observations were made in a particular sequence of ice nucleus measurements was then chosen, and the mean concentrations at that temperature for each day was entered against the appropriate 'synodic decimal'. Moving averages over 0·10 lunar months were taken (roughly equivalent to a 3-day average), as in the rainfall data, giving the curves shown in Fig. 1. In order to compare curves satisfactorily

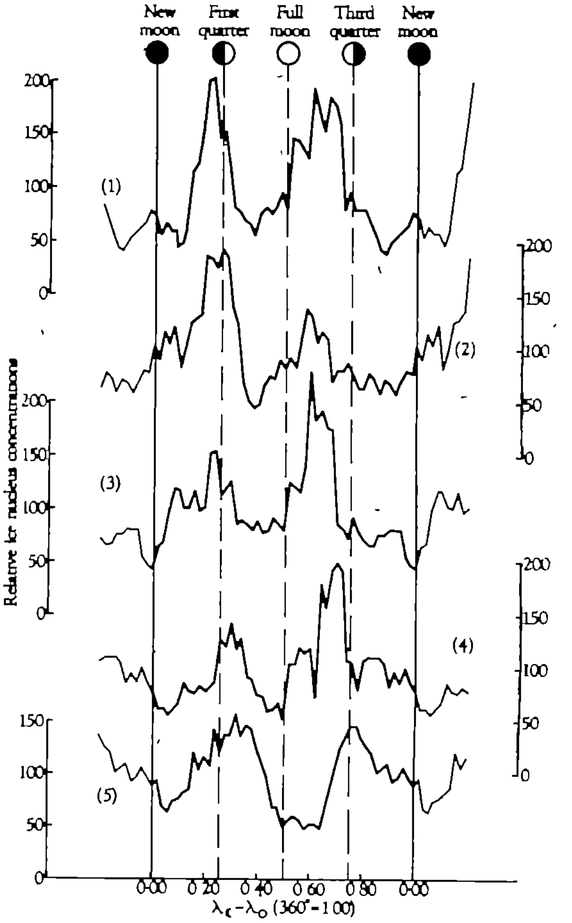

Fig. 1 Relation between summer ice nucleus concentrations in the southern hemisphere and lunar phase

Curve	Location	Time	Instrument
(1)	41° S., 175° E., Wellington, N.Z.	Oct. 1957–Mar. 1958	10 *l* Expansion chamber
(2)	34° S., 151° E., Sydney, Australia	Nov. 1958–Jan. 1959	Continuous automatic cold chamber
(3)	34° S., 151° E., Sydney, Australia	Oct. 1956–March 1957	10 *l* Mixing chamber
(4)	26° S., 153° E., Caloundra, Australia	Nov. 1956–Feb. 1957	10 *l* Mixing chamber
	25° S., 114° E., Carnarvon, Australia	Nov. 1955–Feb. 1956	1 *l* Mixing chamber
(5)	23° S., 14° E., Swakopmund, South-West Africa	Nov. 1956–Jan. 1957	3·5 *l* Expansion chamber
		Dec. 1957–Jan. 1958	10 *l* Expansion chamber

the resulting concentrations were expressed as percentages of the mean for the lunar month.

The result is as surprising as the rainfall discoveries. In every case, there are two distinct maxima in the lunar month, about first and third quarters of the Moon, and the total range is three or four to one, even with the smoothing used. There appears to be a slight shift with latitude, the peaks occurring later nearer the equator (the curves 1–5 are arranged in order of decreasing latitude).

It is apparent, therefore, that, in addition to the effect on rainfall, the Moon has a large effect on the freezing nucleus count. It is well known that the effect of the Moon on other meteorological variables like barometric pressure, surface temperature, is extremely small; the implication is strong, therefore, that the effect on the freezing nucleus count does not originate in the lower atmosphere. However, a possible mechanism is that the Moon in some way controls the incoming meteor rate and so affects the number of freezing nuclei falling into the lower atmosphere. This possibility will be examined in a forthcoming paper.

In the meantime it is interesting to compare the summer rainfall of a continental climate (on which ice nuclei are likely to exert their greatest influence) with those in Fig. 1. In Fig. 2 the daily rainfall of Alice Springs (lat. 24° S., long. 134° E.) during 1873–1952 has been analysed in the same way as the ice nucleus data.

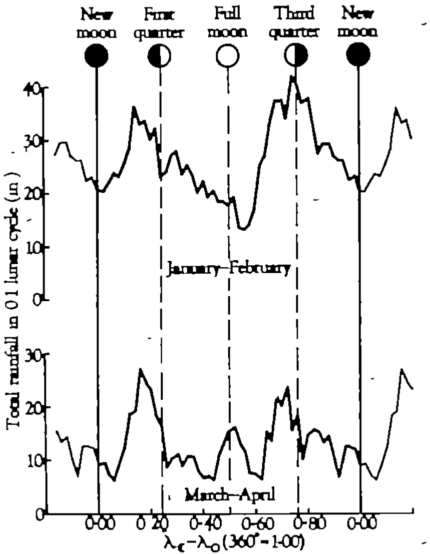

Fig. 2. Relation between total daily rainfall at Alice Springs and lunar phase

The variations are remarkably similar to those of Fig. 1 (and those of the earlier papers) and show that the effect is present not only in the heaviest rainfalls but also in the total daily rainfall at a suitable location. The extreme range of three or four to one in the rainfall is the same as in the ice nuclei, suggesting that on the average there is a progressive increase in rainfall with increase in the ice nucleus count.

I thank the U.S. Weather Bureau for its tables of decimal ephemeris of Sun and Moon which were used for the figures, and the Director of the New Zealand Meteorological Service for the Wellington ice nucleus measurements which have not been published previously in detail.

PHYSICS

Re-entrant Motion in Special Relativity

Phipps[1] has shown that for a disk rotating with edge velocity v, the 'round trip' velocity $v_{rt} = v(1-v^2/c^2)^{-1/2}$ where v_{rt} = circumference of disk/period of revolution. The following argument derives a similar relationship between observed velocity and 'round trip' velocity for linear 'to-and-fro' motion.

Consider two rods AB and CD, each of rest length x, which slide along each other. Initially (as viewed from C) the rods are end to end, B touching C. A and C (also B and D) approach each other at relative velocity v. When an observer at C sees A reach C, the relative motion of the rods is reversed. C measures the time from B leaving C to B returning to C. Because of the relativistic contraction of length, C initially observes A at a point P at rest relative to C and distant $x(1-v^2/c^2)^{1/2}$ from C. (This is equivalent to stating that C observes the length of AB to be $x(1-v^2/c^2)^{1/2}$.) As AB is moving with observed velocity v, the time observed by C for A to reach C is $(x/v)(1-v^2/c^2)^{1/2}$. This is also the time C observes for the return of A to P. When C observes A at P, he also observes B back at C. Hence C measures the time of B's journey as $(2x/v)(1-v^2/c^2)^{1/2}$. Now an observer initially coincident with B and C, and in whose frame of reference AB and CD have equal and opposite velocities, will observe A reach C and B reach D simultaneously. Hence if A reaches C, B must reach D. But in C's frame of reference $CD = x$ and the distance travelled by B is $2x$. It follows that C measures the 'round trip' velocity of B to be $v_{rt} = v(1-v^2/c^2)^{-1/2}$.

It is of interest that the time observed by C for the round trip equals the time observed by C on a clock mounted on B (ref. 2). The clock paradox thus does not exist.

I thank Dr. T. E. Phipps for his comments, and for his encouragement to publish this work.

Pulsed Gaseous Maser

Optical maser oscillation has been obtained during the recombination period following a pulsed radiofrequency or d.c. discharge in helium mixed with either neon or carbon monoxide at wave-lengths of 1·153μ and 1·069μ, respectively. No oscillation occurs during the 10 μsec excitation pulse although in pure neon a period of apparent optical gain and low-power oscillation at about 1·15μ is observed during the pulse.

The usual near-confocal mirror[1] system is used containing a quartz discharge tube 1 m long and 16 mm or 2 cm internal diameter having end windows at the Brewster angle. The tube has been excited either by a high-power S-band magnetron or by d.c. pulses of about 1·5-kV, 20 amp, 10 μsec fed in through tungsten electrodes sealed in side arms of the quartz tube. Pulse repetition rates of up to 1 kc/s have been used for the d.c. excitation.

With the helium/neon mixture the optimum gas pressures appear to be about 1 mm and 70μ mercury respectively, when the oscillation reaches its maximum power of more than 1 W at 30–80 μsec after the end of the excitation pulse and the oscillation pulse then has a half-power width of 40–50 μsec. With S-band excitation it is also possible to obtain powers of about 0·5 W at 1·153μ wave-length when the helium pressure is raised to more than 8 mm. The half-power width of the oscillation pulse is then about 30 μsec and the pulse occurs immediately after the excitation pulse.

The optimum conditions for helium mixed with carbon monoxide involve gas pressures of 2 mm and 8μ mercury respectively. Peak powers of 0·7 W at 1·069μ wavelength are produced about 30 μsec after the excitation pulse and the half-power pulse width is about 40 μsec.

The unusually high powers obtained are thought to be due to the ease with which a high density of 2^3S metastable helium atoms is formed during the recombination of a well ionized helium plasma[2]. Moreover, the high metastable density is obtained without a correspondingly high electron density. These conditions are particularly favourable for producing a population inversion in neon by resonant exchange processes[3].

With carbon monoxide instead of neon, the energy required to dissociate the molecule into a ground state oxygen atom and a carbon atom excited to the $3p^3D$ level is 0·06 eV less than the excitation energy of the metastable helium 2^3S, and a nearly resonant condition for this process is established. The observed wave-length of 1·069μ agrees well with the permitted radiative transition in carbon from the $3p^3D$ state to the $3s^3P^\circ$ state.

The $CI3p^1P$ level being just below the $CI3p^3D$ is also suitable for selective population by this dissociative mechanism. Oscillation originating from this level has been observed by L. E. S. Mathias at these laboratories[4] in a continuously excited helium/carbon monoxide mixture. The lower level is $3s^1P^\circ$ and the wave-length 1·454μ.

This, together with the fact that neither of these upper levels is optically connected to the ground state, is indicative that these oscillations are produced by the dissociative mechanism proposed above, and not by direct electron excitation.

We are indebted to R. S. A. Thorn for performing much of the experimental work. Acknowledgment is made to the Admiralty for permission to publish.

Growth of Positive Channels in Non-uniform Fields during Impulse Breakdown

THE investigation reported by Menemenlis[1] under the same title as a communication to *Nature* of June 27, 1962, has been continued at the laboratory so that some more concrete results concerning the growth of positive channels can now be communicated.

The channels investigated were produced in an 18-cm non-uniform field air gap by applying 1/50 μsec chopped impulse voltages of a crest value of the full wave lying between that causing without chopping 100 per cent breakdown and that exceeding this value by 20 per cent.

The gap consisted of a small sphere, 5–15 mm in diameter, fixed at one end of a 75-ohm coaxial cable and a circular disk 30 cm in diameter, directly connected to the negative high-voltage terminal of the front capacitor of a single stage 200-kV impulse generator whose positive pole was earthed. The coaxial cable was earthed through a 68 + 7 ohm (75 ohm) attenuator. The voltage drop of the predischarge current (that is, of the first corona discharge and of the chopped channel) across the 7 ohm part of the attenuator was applied on the upper beam pre-amplifier of a double beam, Model 555, Teletronix oscillograph to obtain faithful recordings of the time variation of this predischarge current. In addition, a mixed divider, consisting of a 1,000 ohms resistor in series with a 0·5 μH inductance, was connected in parallel to the 7 ohms part of the attenuator. The resistance end of this divider was connected with the upper point of the 7 ohms resistance of the attenuator while its inductance end was earthed. The voltage drop in the inductance, which is practically proportional to the current slope, was applied on the lower beam pre-amplifier of the oscillograph to register the time variation of di/dt.

By correlating both the faithful current records and the current slope records with corresponding photographs of the channels taken in the way described in the aforementioned communication, the following results regarding the propagation mechanism of the positive channels could be obtained.

The average velocity of the channels at various stages of their propagation was found to vary between 2 and 15 cm/μsec, this being in accordance with the results obtained during previous investigations.

The propagation of the channel is effected in steps. At the end of each step a corona burst discharge having several streamers paves the formation of the following step. The current impulses of these successive corona discharges are weaker than that of the first corona pip, which is responsible for the formation of the numerous stems on the positive electrode; but they are comparable to the current corresponding to each stem.

Under the experimental conditions given here, the channels' steps have a length varying between 0·5 and 1·5 cm. Longer steps were rarely observed. They can then reach lengths up to 4 cm.

As a rule, the corona streamers preceding each successive step become thinner and their number increases as the channel proceeds towards the negative disk.

The time-intervals between successive corona discharges vary from 0·05 to 0·6 μsec. The smaller the time interval, the shorter the length of the step and the smaller the magnitude of the electric charge corresponding to the corona current impulse.

The front of the initial corona current impulse lasts some 10^{-2} μcoul. The successive corona impulses occurring during the progress of the channel are less steep; their front duration can reach values up to 0·2 μsec.

The average current through the gap, as it is known, is exponentially increasing during the development of the channel. The current jumps caused by each of the successive coronas vary between 0·5 and 1·5 amp and are superposed to the average current.

The steepness of the current impulses due to the successive corona discharges is of the order of 10 amp/μsec.

The electric charge that corresponds to each of the successive corona impulses shows a considerable variation; the values obtained are from the order of 0·005 to that of 0·1 μsec. They are, however, comparable with those corresponding to a single stem produced on the anode surface by the initial corona pip.

Four characteristic types of channels could be distinguished among several hundreds of photographs.

(1) Single channels presenting practically no branching; (2) single channels split up on their way to the cathode into two strong channels; (3) multibranched channels. In one case, six developing branches out of a common trunk have been recorded; (4) twin channels, that is, two separate channels of comparable length and brightness starting from different points of the sphere.

As it has been already pointed out[1], the application of the correlation method to study the channel development is mainly feasible only in the case of single, practically unbranched, channels.

An important question arises now concerning the physical phenomenon that is associated with the stepped propagation of the positive channel during the impulse breakdown in non-uniform fields. The experience of a great number of experiments conducted so far shows that this propagation can reasonably be interpreted as follows:

It has already been mentioned that the gaps investigated were directly connected to the front capacitor (4,140 pF) of the impulse generator. Oscillograms of the gap voltage taken during the growth of the channel showed no appreciable differences when compared, up to the chopping time, with the no-load impulse voltage of the generator. This is due to the fact that the charge drawn from the capacitor during the channel propagation is negligible compared with the charge stored in it, and therefore the voltage across the gap is practically independent of the channel current. On the other hand, voltage drops were avoided by the absence of any series resistance in the gap circuit. Hence, it is reasonable to conclude that the stepped propagation of the channel should be attributed to the discharge phenomena occurring during its growth and not to any voltage drops or fluctuation caused by the circuitry. The presence of a series resistance would, of course, affect considerably the time constants and the magnitude of the phenomena involved.

Breakdown occurs when the channel reaches the negative electrode and bridges the gap. This is possible when the crest value of the impulse voltage is, at least, as high as the minimum impulse breakdown voltage of the gap. Under this voltage, and either when the impulse voltage approaches its crest or during the first microseconds of its tail, the first corona discharge occurs that produces a stem able to form the starting point of a channel. The meaning of this is that a notable progress of a channel towards the cathode is then possible, when the first corona occurs under a voltage value comparable with the minimum impulse breakdown voltage of the gap.

Calculations of the field strength in front of the positive electrode of gaps with very pronounced non-uniform fields, as those investigated, subjected to the minimum breakdown voltage, led to values of 70 kV/cm or more, that is, to values that are by far higher than the dielectric resistance of the atmospheric air, which is roughly 30 kV/cm. Hence, the first corona discharge, which is followed by a stem able to lead to the formation of a channel advancing in the gap, must jump from a point of the positive electrode where the field strength has at least the above calculated value. Corona discharges can also occur, of course, under lower field strengths; they have been observed during this investigation even by field strengths on the positive electrode of about 40 kV/cm, but it is believed they are also possible by field strengths slightly exceeding 30 kV/cm. However, these weaker corona discharges are not able to pave the formation of a stem sufficiently long and hot for the further evolution of a channel.

It is well known that the channel starts from a point of the stem situated near its end. It has been observed during this investigation that the first channel step occurs after a corona discharge has jumped from this point; a strong streamer of this corona discharge is then transformed to this first channel step. The next step is produced in the same way: a corona jumps from the end of the first channel step and one of its streamers is transformed to the second channel step. This process is repeated many times until the channel reaches the negative disk or, eventually, until it stops earlier.

It has been deduced from many oscillograms taken during this investigation that, under gap voltages able to cause a notable progress of a channel, both the current intensities and the electric charges involved during the corona discharges of the successive steps are comparable with the corresponding magnitudes of the first corona streamers that start from various points of the positive electrode and become the basis of the stems. Hence, it might be suggested that all corona discharges leading to the formation of the channel steps are roughly as strong as that creating the stem which, in a way, is the first channel step and, therefore, that they jump from points of the stem or of the channel steps where the field strength reaches a value comparable to that producing on the positive electrode the first corona burst, that is, 70 kV/cm or more.

As stated here, weaker corona discharges have also been recorded. They were starting from points of lower field strength but they were not able to lead to a notable progress of a channel. At the limit, even a slight excess of the critical values of 30 kV/cm, of the field strength on the stem or on the channel steps surface should be able to produce a small discharge. This discharge, however, would cease to advance as soon as the field strength at its boundary reaches the minimum value required for ionization, that is, 30 kV/cm. The consequence should be that the field strength on or near the surface of the stems or of the channel steps would never reach with weak coronas the value of about 70 kV/cm which is indispensable, as mentioned here, for a further channel propagation. Therefore, it seems reasonable to suggest that a phenomenon should take place that causes a sudden jump of the field strength on the streamers forming the stems or on the channel steps during their creation from a value of 30 kV/cm to a value of the order of 70 kV/cm. Such a phenomenon could be a sudden 'constriction' of that part of the corona streamers that have been sufficiently heated by the electronic current flowing through them to the positive electrode, so that the high-temperature plasmas of the stems or the channel steps are formed. As a matter of fact, numerous constriction cases could be noticed after a careful examination of a great number of photographs of chopped channels. When they are taken under good focusing and sensitivity condition, they show very distinguishingly bright thin channels surrounded by a quasi-cylindrical space showing a much weaker brightness, which, obviously, was previously occupied by a preceding corona streamer. Hence, it might be concluded that such streamers have been constricted to form the thin channels. In many photographs, constricted sections of channels are followed by corona streamers which are partly ready to be constricted. A conical space connecting the two stages shows a gradually decreasing brightness from the narrow channel to the wider streamer.

The constriction causes a sudden decrease of the diameter of the cylindrical discharge space of a corona streamer from the order of a few millimetres to that of a few tenths of a millimetre, that is, the diameter of the stems or the channel steps. This sudden reduction of the diameter, as well as the abrupt decrease of the gradient along the discharge space, cause the necessary sudden increase of the field strength around them so that it reaches at a point near their end the level required of about 70 kV/cm.

Hence, during the progress of the channel conditions are repeatedly established for the production of corona discharges that are strong enough to create the next channel steps by means of new constrictions.

Such constrictions phenomena, known also under the name of 'glow to arc transitions'[2,3], are believed to occur in gases under low pressures or pressures of the order of 1 atm. Bruce[4] has suggested that a constriction occurs during the formation of the leader-stroke darts in lightning discharges. Constriction is supposed to occur during the formation of positive channels along the traces of the first streamers of positive gliding discharges[3]. The phenomena involved during the transitions are not very well known[2] but some conclusions can be drawn from the experimental data available: (1) the time of the constriction can be as short as 0·01 μsec; (2) the electric conductivity of the discharge path increases very much during its constriction; (3) the voltage gradient along the discharge path may fall from values of the order of 1,000 V/cm, able to conserve high-pressure glow discharges, to values of an arc discharge which are of the order of 50 V/cm. Such differences in the gradient values of the corona streamers and of the channel paths are believed to exist by many authors.

This investigation is continuing with the financial support of the Royal Hellenic Research Foundation. I thank Mr. Ch. Menemenlis for several discussions and for his collaboration in performing the experimental work.

CHEMISTRY

Polarographic Behaviour of the Hexa-amminechromium(III) Ion: Role of Hydrogen Ions

Hexa-amminechromium(III) ion in acetate buffer solutions is reduced at the dropping mercury electrode, and gives two polarographic waves. The first wave, which is well defined, is considered to be a one-electron reduction of Cr(III) to Cr(II)[1]. Its half-wave potential at 25° C was found to be $-0{\cdot}97_5$ V *versus* saturated calomel electrode in 0·1 M acetate buffer solution which contained 0·9 M potassium chloride and 0·005 per cent gelatin (Fig. 1, curve *a*). The limiting current of this wave was diffusion-controlled and proportional to the concentration of the complex ion up to 5 mM. Both the half-wave potential and the diffusion current remained constant when the *p*H was varied from 4·5 to 5·45. No change was observed when potassium chloride was replaced by ammonium chloride at the constant ionic strength. The plot of log $i/(i_d - i)$ *versus* E, where i means the average current, i_d, the average diffusion current, and E, the potential of the dropping mercury electrode, gave a straight line with a reciprocal slope of 64 mV, whereas the examinations with Kalousek's circuit and alternating current polarograph showed that this wave has nearly irreversible character.

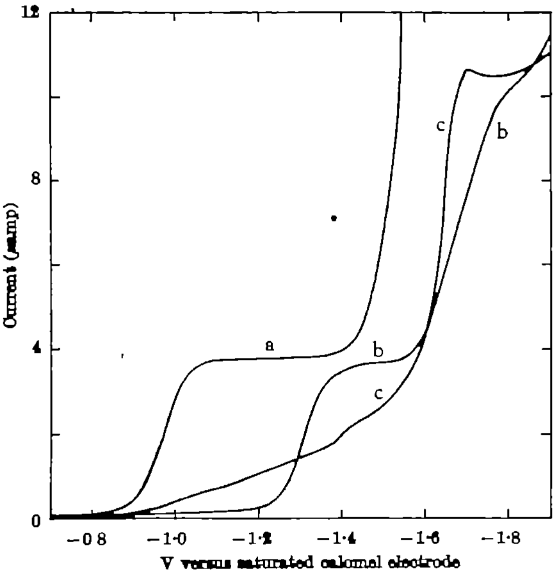

Fig. 1. Polarograms of 1 mM $[Cr(NH_3)_6]^{3+}$ at 25° C in 0 1 M acetate buffer + 0 9 M potassium chloride *p*H 4 6 (*a*); 1 M potassium chloride + 1·56 mM disodium dihydrogen ethylenediamine tetraacetate (*b*); 1 M potassium chloride (*c*). Gelatin was added by 0·005 per cent in all cases

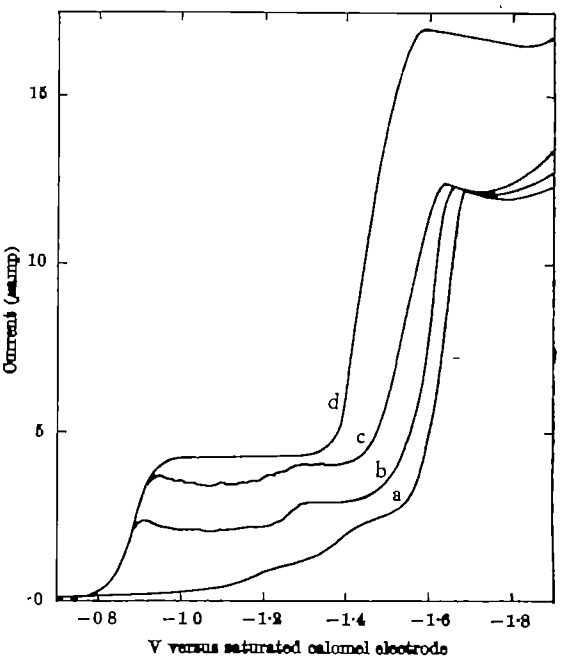

Fig. 2. Effect of hydrochloric acid on the reduction of 1 mM $[Cr(NH_3)_6]^{3+}$ in 0 1 M potassium chloride + 0·005 per cent gelatin + *x* mM hydrochloric acid. *x* = 0 (*a*), 1 0 (*b*), 1 5 (*c*), 2·0 (*d*). In this case current was measured at maximum of current oscillation

In neutral salt solutions, no well-defined one-electron reduction wave was observed (Fig. 1, curve *c*), as has been reported by Maki, Shimura and Tsuchida[2]. The value of the diffusion current at −1·7 V corresponds to a three-electron reduction, that is, Cr(III)→Cr(O). On the addition of hydrochloric acid, the wave at −0·89 V began to appear (Fig. 2). The current at −1·7 V, on the other hand, remained constant until the acid concentration reached a certain critical value; the wave due to hydrogen ion discharge appeared only when this critical concentration was exceeded. This phenomenon is an example of the 'interfering electrode reactions' described by Kolthoff and Lingane[3]. In the present case, hydrogen ions diffusing up to the electrode are neutralized by the ammonia molecules which are liberated by the reduction of hexa-amminechromium(III) ion; reduction of one complex ion will produce six ammonia molecules. The ratio of the critical acid concentration to the concentration of $[Cr(NH_3)_6]^{3+}$ was found to be 1·66, which is in agreement with the value calculated by the equation:

$$(C_{H^+}/C_{Cr(NH_3)_6^{3+}})_{crit.} = 6(D_{Cr(NH_3)_6^{3+}}/D_{H^+})^{1/2}$$

where C is the concentration and D is the diffusion coefficient of the respective species. The wave at −0·89 V attained its full development just when the acid concentration reached the critical value. There was no further essential change in the shape of the developed wave when the acid was added in excess. Hydrogen ions seem to play an essential part in the reduction of hexa-amminechromium(III) ion to the divalent state. However, they cannot be involved in any chemical reaction prior to the electron transfer, because the half-wave potential of the one-electron reduction wave was independent of the hydrogen ion concentration of the solution. They rather act as a neutralizing agent of the ammonia molecules which are liberated from the divalent chromium species. When hexa-amminechromium(III) ion is reduced in a neutral non-buffered solution, the liberated ammonia will make the solution layer near the electrode alkaline, and will cause divalent chromium species to precipitate as an insoluble film on the surface of the electrode. In 0·1 M potassium chloride solution, the current in the potential region between −0·6 and −1·3 V was almost independent of the concentration of the complex ion, and the currents at −1·1 and −1·2 V were linearly proportional to the height of the mercury reservoir. The addition of gelatin increased the current between −1·0 and −1·35 V. These observations support the foregoing conclusion. The fact that the electrode is covered with the insoluble film was confirmed by the observation of the current-time curves during the period of a mercury drop.

It is, therefore, expected that any reagent which can keep divalent chromium from precipitating will make the one-electron reduction wave appear. The polarogram of 1 mM $[Cr(NH_3)_6]Cl_3$ in a neutral salt solution (1 M potassium chloride) containing 1·56 mM of disodium dihydrogen ethylenediamine tetraacetate and 0·005 per cent gelatin (Fig. 1, curve *b*) showed that this is the case.

That the well-defined one-electron reduction wave does not appear in neutral salt solutions though it appears in acid media is a general character of those chromium(III) complexes that have one or more basic ligands, unless the corresponding divalent complexes are stable enough to be maintained in solution. In fact, the following complex ions gave the one-electron reduction wave in acetate buffer solutions (with 0·005 per cent gelatin added), and did not in neutral salt solutions: $[Cr(H_2O)(NH_3)_5]^{3+}$, $[Cr(en)_3]^{3+}$, *trans*-$[Cr(NCS)_2(en)_2]^+$, *trans*-$[Cr(NCS)_2(pn)_2]^+$, $[Cr(ox)(en)_2]^+$, and *trans*-$[Cr(NCS)_4(NH_3)_2]^-$, where en, pn and ox represent ethylenediamine, propylenediamine and oxalate, respectively. On the other hand, a well-defined one-electron reduction wave of Cr(III)→Cr(II) is observed in potassium chloride or sodium chloride solutions for *tris* (dipyridyl)chromium(III)[4], hexathiocyanatochromate (III), and ethylenediamine tetraacetatochromate(III) ions.

We thank Dr. E. Kyuno and Miss K. Ebata for their assistance in the course of this study.

Molecular Addition Compounds of Polycyclic Derivatives of Cinnoline

POLYCYCLIC derivatives of cinnoline are known to form molecular addition compounds with picric acid[1]. Contrary to the report by Slack and Slack[2], I find that benzo[*c*]cinnoline, in common with its methyl derivatives[3], forms a mono-picrate. My compound (found, C, 52·9; H, 2·8; N, 16·8; $C_{18}H_{11}N_5O_7$ requires C, 52·9; H, 2·7; N, 17·1 per cent) has the same melting point as that reported by Slack and Slack, who based their formula solely on a nitrogen content of 17·8 per cent.

The polycyclic derivatives of cinnoline also form addition compounds with trinitrofluorenone in ethanol. These were found to be 1 : 1 addition compounds except in the case of benzo[*f*]naphtho[2,1-*c*]cinnoline, which formed a 1 : 2 compound.

Orchin[4] has suggested that the melting points of molecular addition compounds of the aromatic hydrocarbons, relative to those of the hydrocarbon itself, can be taken as a measure of the effectiveness of the intramolecular forces between the two molecules. From Table 1 it can be seen that the addition compounds of the polycyclic cinnolines melt at temperatures close to or above the melting point of the cinnoline except in the case of benzo[*f*]naphtho[2,1-*c*]cinnoline. This cinnoline is non-planar, as a result of intramolecular overcrowding; and it is evident that this non-planarity reduces the effectiveness of the intramolecular forces responsible for compound formation. The non-planarity of the molecule may also be responsible for the formation of a 1 : 2 compound with trinitrofluorenone, since the cinnoline would present two planes for attachment of molecules of trinitrofluorenone.

Solvation of the Proton in Humic Acids

Tuck and Diamond[1] have described the primary solvation of the proton in the solvent extraction of strong acids by basic organic solvents from dilute acids. Their work gives evidence that the hydronium ion, H_3O^+, is a trihydrated hydronium ion, $H_3O(H_2O)_3^+$, in dilute acids. Others have given evidence from X-ray[2], nuclear magnetic resonance[3], infra-red[4], and Raman[5] studies for the existence of the hydronium ion, H_3O^+, in the solid state.

In this communication, we wish to report the apparent existence of trihydrated hydronium ion in humic acids in the solid state.

Preparation of humic acids. North Dakota lignite (supplied by the Bariod Division, National Lead Co., Houston, Texas) was extracted with 2 N sodium hydroxide[6] at room temperature until the extract was light brown or clear. The aqueous sodium humate solution was centrifuged, decanted and treated with hydrochloric acid until a *p*H of 3 was reached. At this point, the humic acids were quantitatively precipitated. After separating the humic acids by centrifugation they were washed with distilled water and dried at 105° for 12 h.

The analyses of these acids are shown in Table 1.

Table 1

	Ultimate analysis					
	%H	% C	% N	% O	(diff.) % S	% Moisture
Lignite	4·20	45·40	0·82	29·04	2·06	12·23
Humic acids	4·14	59·56	0·70	32·4	1·14	3·56
Decarboxylated and dehydrated humic acids	3·62	61·71	0·72	31·3	1·35	1·37

Decarboxylation method. 79 g of humic acids were supported on glass wool in a 38 × 280 mm electrically heated glass column[7]. Two thermometers were inserted into the column to measure the temperature of the humic acids at two depths. Glass wool was placed on the top of the humic acids to prevent the loss of fine particles from the column.

A variable voltage regulator was used to maintain the temperature of the column at 150°. Anhydrous carbon dioxide-free nitrogen was introduced into the column at a rate of 14 l./h. Carbon dioxide and water were quantitatively determined in the exit gases from the column by absorption in U-tubes packed with ascarite and anhydrous calcium sulphate.

The moles of evolved carbon dioxide and water over 65 h of heat treatment at 150° are shown in Fig. 1.

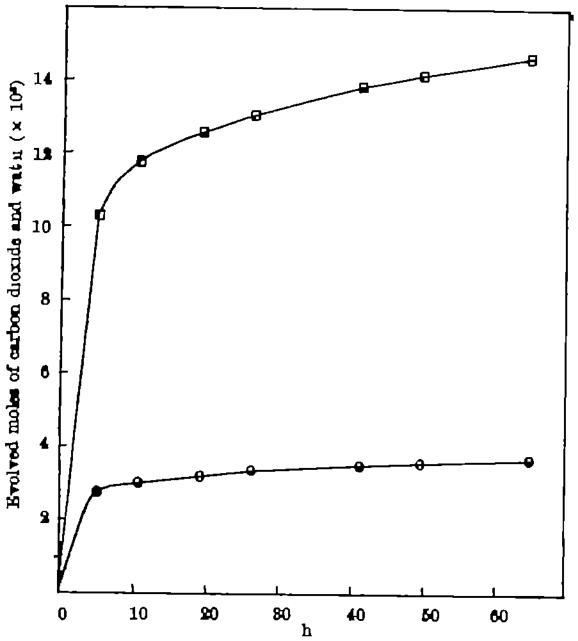

Fig. 1. Effect of heating humic acids at 150° C and 14 l. of nitrogen per h. Moles of carbon dioxide (○) and water (□) versus time (h)

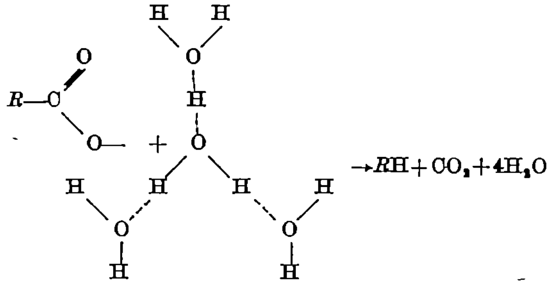
The mole ratio of evolved water to carbon dioxide was about 4. The rate of decarboxylation and dehydration decreased with time. The analyses of the humic acids after 65 h of heat treatment are given in Table 1.

The combined water of humic acids appears to be associated with the carboxyl groups as evidenced by the almost constant ratio of water to carbon dioxide (4 : 1) found in the evolved gases on heat treatment at 150°. The strong co-ordinate solvation in the solid state is postulated, and is very similar to that found by Tuck[1] in his work on extracts from aqueous solutions into organic solvents of strong acids. The primary solvation of the hydronium ion[1] and decarboxylation and dehydration of humic acids are indicated as follows (where *R* is the remainder of the humic acid molecule):



These results appear contrary to those expected. Humic acids, being weak acids, should be in a non-ionized molecular form. Also, one might expect that in the solid state carboxylic acids would be un-ionized.

This work was supported by the Bariod Division, National Lead Company, Houston, Texas.

BIOPHYSICS

Effect of Oleic Acid on the Mobility of Human Red Cells, and its Effect on Human Serum Protein Fractions

THE higher fatty acids (C-18 acids such as oleic, ricinoleic, arachidonic, etc.) exist both in the adenocarcinomas of the *C3H* mouse[1] and in at least some human tumours[2]. They also occur in normal mouse and human tissues[3], where they are combined, somewhat like the fatty acids in tumours, with lipid and protein inhibitors about which little is known. This communication is concerned with the question whether oleic acid (taken as an example of the higher fatty acids) affects the electrical mobility of human red cells (*A*, below), and whether it interacts with human serum protein fractions.

(*A*) *Method.* One volume (about 3 ml.) of M/50 oleic acid in ethanol is added to 2 volumes of Dole buffer at *p*H 8·6, and is dialysed for 18 h or more at 20° C against large volumes of the same buffer. A suspension of washed human red cells is diluted with the buffer so as to have a volume concentration of 0·08. To 10 ml. of the buffer is added 0·1 ml. of this suspension. When drawn up into the vertical electrophoresis cell[4], such a suspension provides about 20 red cells per field. It is important to avoid working with much more concentrated suspensions, which provide an example of a phenomenon in which the mobility is partly determined, not by single cells, but by groups. To 10 ml. of this suspension is added 0·1–0·3 ml. of the dialysed oleic acid sol, and the mobility of the cells is determined before and after the addition. Larger quantities of sol are lytic. Alternatively the red cells can be suspended in serum or in serum to which the oleic acid sol has been added.

(1) The mobility of washed human red cells in Dole buffer at *p*H 8·6 is remarkably constant at 1·3 μ/sec/V/cm. The addition of 0·15 ml. of oleic acid sol to 10 ml. of a suspension of washed human red cells reduces the mobility to 0·98 μ/sec/V/cm, or by 25 per cent.

(2) If the red cells are suspended in serum which has been dialysed against Dole buffer at *p*H 8·6, the mobility is a little less than 1·3 μ/sec/V/cm, because the viscosity of serum is slightly greater than that of the buffer. Addition of 0·1 ml. of oleic acid sol to 10 ml. of a red cell suspension in serum reduces the mobility by 8 per cent and the addition of 0·2 ml. of the sol reduces the mobility by 15 per cent, that is, the effect of the oleic acid in reducing the mobility is less than when the cells are suspended in buffer alone.

(*B*) *Method.* One part of M/25 oleic acid in ethanol is added to 2 parts of Dole buffer at *p*H 8·6 and then dialysed against a large volume of the buffer for 18 h or more. Because of a volume change, the final concentration of oleic acid is M/100. Serum is dialysed against Dole buffer at the same *p*H for the same time.

Equal parts of the dialysed serum and the dialysed oleic acid are mixed and allowed to stand for 2 h at 22° C. The electrophoretic pattern of this mixture is obtained with the Antweiler micro-Tiselius apparatus at 18° C, and is compared with the pattern obtained with dialysed serum plus one volume of the buffer. A typical result is shown in Table 1, which shows the quantities of the different serum fractions as judged by the areas under their spikes.

The two important points are that the presence of the oleic acid produces an apparent reduction in the quantity of β-globulin, and a corresponding increase in the quantity of albumin plus α_1-globulin. This suggests that the addition of the oleic acid sol confers the mobility of the

Table 1

	$A + \alpha_1$	α_2	β	γ	Total
Serum	126	14	20	17	177
Oleic acid M/100 plus serum	138	11	10	20	179
Differences	12	−3	−10	3	2

albumin plus α_1-globulin fraction on some of the β-globulin fraction. Sometimes a small new spike appears in advance of the albumin spike, as if there were a new fraction with a mobility greater than that of albumin. By using a larger quantity of oleic acid (M/70), the effect on the β-globulin spike is still greater, so that virtually no β-globulin can be demonstrated by this method.

Density and Structure of Alpha-Keratin

A MODEL of the two-phase structure of fibrous α-keratin has been evolved, starting with the α–β fold of Astbury *et al.*[1] and thence via the concept of α-helices to the coiled-coil models of Pauling and Corey[2] and of Crick[3], and at present to the detailed schemes of packing recently proposed by Fraser, MacRae and Rogers[4] and by Johnson and Sikorski[5]. The successive stages of this development have resulted primarily from attempts to give a more accurate explanation of the observed X-ray diffraction patterns. In addition, however, each advance has been judged by its success in explaining the 'high' densities found for keratin, and all have been found wanting because they led to lower crystalline densities than the values actually measured (definitive values given by Fraser and MacRae[6] range from 1·283 g/c.c. for cow horn to 1·335 g/c.c. for echidna quill tip, at 25° C). This reasoning appears to rest on a false analogy with polymers, involving the assumption that the density of the crystalline phase is necessarily greater than that of the non-crystalline phase. Because this assumption is still influencing current thought on keratin ultrastructure it seems worth while to point out three deficiencies in the polymer analogy.

(1) For many polymers, the density in the crystalline phase does indeed exceed that in the amorphous phase (whether liquid or glassy). These are largely non-polar materials where the intermolecular forces are relatively small and the increase in order associated with crystallization is synonymous with denser packing of the molecules. However, when the intermolecular forces are stronger, as in polar materials and, particularly, in hydrogen-bonded systems, the disordered structure may be more dense than the crystalline state. An outstanding example of this is shown by the 10 per cent increase in density when ice melts. Of more immediate relevance is the work of Bradbury[7], who has recently measured density increases of the order of 1 per cent associated with the helix→random coil transition in synthetic polypeptides in solution.

(2) The polymer situation relates to a material composed essentially of a single molecular species. There is now ample evidence that keratin contains at least two distinct molecular fractions with differing amino-acid compositions, as shown by the separation into keratoses or other high- and low-sulphur fractions[8,9]. Although the direct relation of these components to the crystalline and non-crystalline phases in keratin is still controversial, it is reasonable to presume that the two phases will also differ in composition and therefore in density. Johnson and Sikorski[5] have recently noted that α-keratose contains "a greater proportion of the bulky amino-acid residues" and suggest that this argues against the general belief that the α- and γ-fractions are derived from crystal and from matrix respectively, because of the "greater regularity and better packing" in the crystal. This is an important observation; but the corollary is fallacious because "better packing" is not in this case necessarily identifiable with more dense packing.

(3) The high cystine content of keratin is probably derived more from the matrix than from the crystalline microfibrils and the presence of the additional disulphide cross-links implies a considerable relative densification of this phase.

To relate these points to a specific polymer, consider a strip of unvulcanized natural rubber having a density of 0·91 g/c.c. in the amorphous, unstrained state. If this strip is stretched to 700 per cent extension at 0° C, its density increases[10] by approximately 3 per cent. The crystalline density, using Bunn's unit cell[11], is 1·00 g/c.c. so that about 30 per cent by volume of the rubber is crystalline.

If the matrix alone were now to be cross-linked, its density could be increased to a value equal to or even greater than that of the crystallites. In the simplest case where the cross-links are direct —C–C— bridges a volume contraction of 124 Å³ per cross-link has been found[12] which is somewhat larger than the average volume per amino-acid residue in keratin. As there are about nine residues per cystine cross-link in the whole wool fibre, density increases in the matrix of at least 10 per cent are thus conceivable on the basis of cross-linking alone.

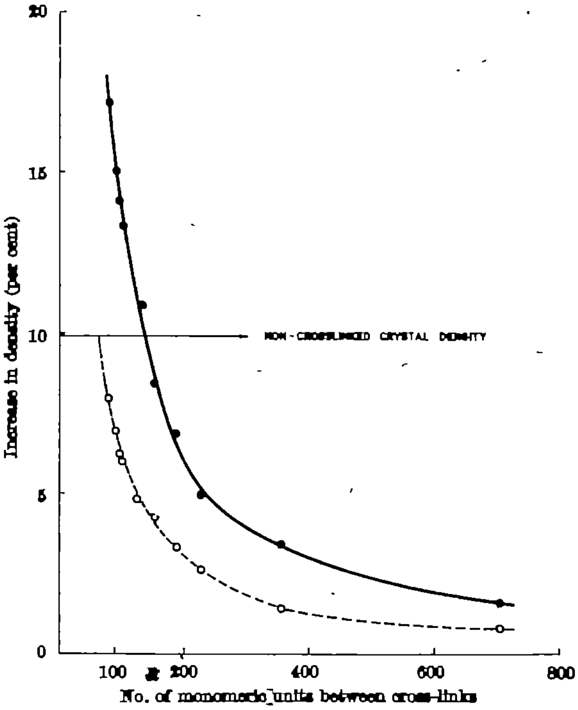

Fig. 1

An even more striking increase in density is observed when the rubber is cross-linked by heating it with sulphur. Fig. 1 shows the variation in density with degree of cross-linking, using the data of Martin and Mandelkern[13]; the degree of cross-linking is represented by n, the number of monomeric units between cross-links, this being estimated by reference to the work of Moore, Mullins and Swift[14]. It can be seen how the density increases rapidly as n decreases towards the levels appropriate to keratin. In particular, the crystalline density is reached at a value of approximately 140 monomers between cross links. As this comparison may be exaggerated by the high density of the sulphur atom, the dotted curve has been drawn in to show the corresponding increase in steric density, that is, the fractional volume occupied by the atoms assuming normal van der Waals radii and covalent bond-lengths. Even on this basis, the crystal density is reached at the comparatively low level of one cross-link per 66 monomers. It should be observed that in this system there is extensive intra-molecular combination of sulphur with the main hydrocarbon chains quite apart from the intermolecular cross-linking[14]. Thus this cross-linked polymer can be denser than its crystalline phase on the grounds of both of the foregoing points (2) and (3).

The foregoing discussion emphasizes the possibility that in keratin the matrix may be denser than the crystallites. It may be noted that Haly and Swanepoel[15] found it necessary to postulate that the matrix in dry wool is the denser component in order to account for the form of their observations of birefringence at different water contents.

BIOCHEMISTRY

Preparation of [^{131}I]-3-Monoiodotyrosine and [^{131}I]-3,5-Diiodotyrosine of Very High Specific Activity

IN the course of work on the extraction of iodinated tyrosines from human plasma and their subsequent estimation, it was necessary to determine the losses which might occur during the series of manipulations. For this purpose we decided to add quantities of [^{131}I]-3-monoiodotyrosine ([^{131}I]-MIT) and [^{131}I]-3,5-diiodotyrosine ([^{131}I]-DIT) small enough to be below the lower limits of estimation by our method but having a sufficiently high [^{131}I]-activity to be counted easily in a well-type scintillation counter.

The highest published specific activities of these compounds we have found in the literature were those prepared by Lemmon, Tarpey and Scott[1] using the method of Harington[2] and Harington and Pitt-Rivers[3] adapted to micro-scale preparations. The specific activities reported are 498 μc./μmole for [^{131}I]-MIT, and 996 μc./μmole for [^{131}I]-DIT. In these preparations the specific activity was of necessity reduced by the addition of carrier iodine-127. The chloramine *T* radioiodination procedure used by Hunter and Greenwood[4] for human growth hormone was therefore adapted to prepare the [^{131}I]-iodotyrosines so far as possible 'carrier free'.

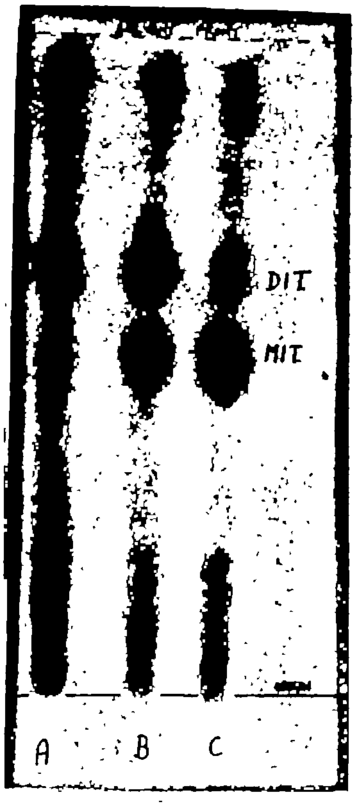

Fig. 1. Autoradiogram of chromatograms of preparations of [^{131}I]-MIT and [^{131}I]-DIT on Whatman No. 1 paper; ascending chromatography in *n*-butanol/2 N acetic acid (1 : 1; equilibrated at room temperature). Run 16 h

All solutions were prepared with de-ionized water, and all the glassware used was, after cleaning, finally rinsed with de-ionized water. However, minute traces of iodine (even a small fraction of a μg), which might be difficult to exclude from glassware and solvents, can multiply many times the actual amount of iodine contained in the 'carrier free' [^{131}I]-iodine solution used in any single preparation. A typical preparation of [^{131}I]-MIT proceeded as follows:

[^{131}I]-iodide in dilute (N/50) sodium hydroxide (2 mc.; 10–20 μl.; carrier and thiosulphate free from Radiochemical Centre, Amersham, Code No. IBS. 3) was added to a solution of L-tyrosine (California Biochem., Res., Corp., *A* grade; 1 μg in 25 μl. borate buffer *p*H 8). A freshly prepared solution of chloramine *T* (B.D.H.; 50 μg in 25 μl. of borate buffer *p*H 8) was then added, the tube stoppered and gently swirled. After 1–2 min, a solution of

Table 1. SUMMARY OF IODINATIONS ILLUSTRATED IN FIG. 1

	L-Tyrosine (μg)	'Carrier free' ^{131}I (mc.)	Per cent total ^{131}I activity appearing on chromatography as	Maximum theoretical yields (μg)	Minimal specific activities mc./μg	c./μmole
A	0·05	2·33	MIT trace DIT − 31	MIT——— DIT − 0·1198	MIT——— DIT − 6·06	MIT——— DIT − 2·62
B	0·10	1·67	MIT − 31 DIT − 38	MIT − 0·1061 DIT − 0·0897	MIT − 4·97 DIT − 7·07	MIT − 1·53 DIT − 3·07
C	1·0	1·75	MIT − 62 DIT − 11	MIT − 1·558 DIT − 0·1948	MIT − 0·696 DIT − 1·012	MIT − 0·214 DIT − 0·438

Aliquots of iodine-131 taken for iodinations were measured with an ionization chamber (type 1383 *A*, General Radiological Ltd., London, with amplifier d.c. type 1388 *B*, Avo, Ltd., London), in which there had been made a previous determination of the total activity of the sample of iodine-131; the absolute value of this sample was given by the Radiochemical Centre, Amersham. An error of about 10 per cent in the measurements was indicated by the difference between the total activity and the sum of the activities of the aliquots.

freshly prepared sodium metabisulphite (B.D.H.; 1·2 mg/ml. in borate buffer pH 8; 100 μl.) was added. When required for ease of subsequent manipulation, the volume of the mixture after reaction was increased by the addition of 0·1 N ammonia in 10 per cent isopropanol.

An aliquot of the reaction mixture was subjected to ascending chromatography in n-butanol/2 N acetic acid (1 : 1), and the dried paper strip was scanned in an argon flow chromatogram counter (Baird and Tatlock Co., Ltd.) to give the percentage of the total activity incorporated into [^{131}I]-MIT. Assuming that all the L-tyrosine had been iodinated, a minimum specific activity could then be calculated. This way of calculation obviates the necessity of assuming a definite abundance of iodine-131 isotopes in the 'carrier free' iodide used in the preparation. These estimates are conservative, and the actual specific activity may be higher.

Fig. 1 gives the autoradiogram of three of our preparations, and Table 1 the relevant data.

For subsequent tracer work the spots were cut out, eluted with 0·1 N ammonia in 10 per cent isopropanol, and stored in a deep freeze. The identity of the material was checked by re-chromatography and autoradiography, running markers alongside the eluted material, which were revealed by spraying with ninhydrin. Chromatograms and autoradiograms of the eluted material mixed with various markers were also used for the identification of the spots.

Work is in progress on the stability under various conditions of these very highly active preparations, and also on the extension of the method to the radioiodination of various thyronines.

These results are part of an investigation on the occurrence of iodotyrosines in human plasma; we thank the Medical Research Council for a grant in support of this work.

We also thank Sir Brian Windeyer, Prof. J. E. Roberts and Dr. E. S. Williams for their interest, and Prof. A. Neuberger and Dr. R. Pitt-Rivers for reading the manuscript and for helpful discussions.

Effect of Acetaldehyde on the Resorcinol Test for Fructose

The Seliwanoff colour reaction of ketohexoses with resorcinol and hydrochloric acid is the basis of several quantitative procedures for the determination of fructose in biological materials in which the absorbance is measured at 470 mμ[1], 480 mμ[2], 490 mμ[3], 510 mμ[4], 520 mμ[5], and 540 mμ[6]. Roe reported that the addition of ethanol[5,7] or acetic acid[5] to the reaction mixture has the effect of increasing the absorbance of the coloured product at 520 mμ. The cause of the effect produced by these solvents is obscure. Roe suggested that the dehydrating conditions of the reaction were improved by introducing ethanol[7] and that the hydrolytic properties of the reagent were improved by the addition of acetic acid[5]. While some workers have noted that the quality of the solvents affected the absorbance at 480 mμ[2,8] and the absorption spectrum[8], the fact that impurities in these solvents may be largely responsible in some cases for the effect attributed to the solvents themselves seems to have passed unnoticed. In this communication we wish to direct attention to the effect produced by acetaldehyde, an impurity in commercial acetic acid[10] and ethanol[11], on the colour formation in the resorcinol test.

The resorcinol test which was developed by one of us[12] to determine 3,6-anhydrogalactose in marine algal polysaccharides was modified to examine the effect of adding acetic acid, ethanol and acetaldehyde on the visible absorption spectrum of the coloured product. The reagent was prepared by adding 100 ml. of 12 M hydrochloric acid to 10 ml. of $1{\cdot}2 \times 10^{-2}$ M resorcinol in aqueous solution. The reagent (10 ml.) was put into a test-tube containing 1 ml. of $1{\cdot}8 \times 10^{-4}$ M fructose in aqueous solution and 1 ml. of the additive being tested. The tube was covered with a glass marble and the reaction mixture was heated for 10 min at 80° C.

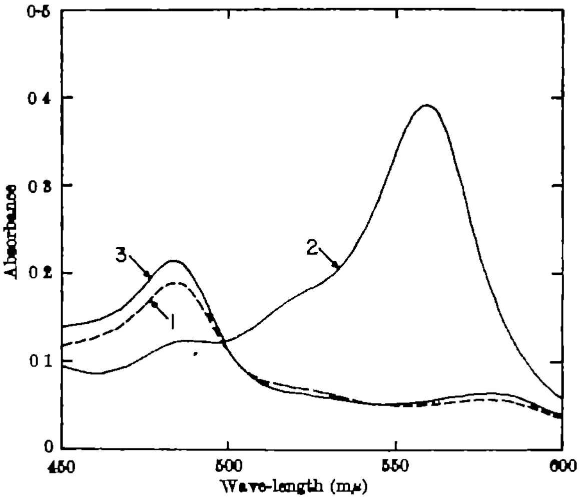

Fig. 1. Absorption spectra of coloured products formed in resorcinol test using as additives (see text for details of procedure): 1, water; 2, commercial acetic acid; 3, purified acetic acid. Spectra determined with a Beckman *DK-2* spectrophotometer using a 10-mm light path

Fig. 1 shows absorption spectra obtained using, as additives, water (curve 1), commercial acetic acid (curve 2), and the same commercial acetic acid after purification by fractional distillation (curve 3). Thus purification of the acetic acid resulted in shifting the wave-length of maximum absorption (λ_{max}) from 555 mμ to 480 mμ and decreasing the absorbance at λ_{max} from 0·4 to 0·2. The similarity between the absorption spectra obtained using water (curve 1) and purified acetic acid (curve 3) should be noted. Spectra similar to those described for acetic acid were obtained with absolute ethanol. From these results we conclude that purified acetic acid and ethanol have a negligible effect on the Seliwanoff reaction carried out according to our procedure.

A consideration of known impurities present in commercial acetic acid and ethanol led us to study the effect of acetaldehyde on the colour reaction. When purified acetic acid (curve 3) containing 0·06 μmole of acetaldehyde per ml. was used, the absorption spectrum was identical to that obtained with commercial acetic acid (curve 2). It was shown that the shift in λ_{max} is independent of the presence of organic solvents in the reaction mixture since it was also obtained when 1 ml. of an aqueous solution containing 0·06 μmole of acetaldehyde was used in the foregoing procedure. Further work was carried out with 1,1-diethoxyethane rather than acetaldehyde since the former compound is less volatile and more stable at room temperature, and is readily hydrolysed to acetaldehyde with a mineral acid catalyst. Its effect on the colour reaction was indistinguishable from that of acetaldehyde. The absorbance at 555 mμ was dependent on the concentration of 1,1-diethoxyethane in the reaction mixture, maximum absorbance being obtained when equimolar amounts of 1,1-diethoxyethane and fructose were present. Beer's law was obeyed unless the molar ratio of 1,1-diethoxyethane to fructose was less than one.

The complete details on factors affecting the production of colour in the resorcinol test for the determination of fructose and 3,6-anhydrogalactose will be presented in forthcoming publications. In view of our results, and since a large number of colour reactions used for detecting and determining carbohydrates is based on the condensation of phenols with products formed from sugars by the action of acids[13], it may be expected that the absorption spectra of other colour reaction products would be affected by aldehyde impurities in organic solvent.

The absorbance at 555 $m\mu$ in the resorcinol test for fructose is not only affected by acetaldehyde but also by other *n*-aliphatic aldehydes. This is the basis for a sensitive procedure for determining *n*-aliphatic aldehydes which will be published shortly.

Lipase and Glycerokinase Activities in the Adipose Tissue of Obese–Hyperglycæmic Mice

IT has previously been reported that free fatty acid mobilization from the adipose tissue of hereditary obese–hyperglycæmic mice after incubation with epinephrine or fat-mobilizing substance[1] or prolonged fast is far smaller than is seen with tissue from non-obese litter-mates[2,3]. It has also been shown that lipogenesis from acetate in adipose tissue from this animal proceeds at 10–15 times the normal rate[4]. The diminished free fatty release and the increased lipogenesis from acetate occurring in spite of a decrease in glucose uptake[5] and utilization[2,3] suggested to us that this syndrome might entail two abnormalities, possibly interrelated: an impaired lipolytic activity directly related to the epinephrine-sensitive lipolytic system in adipose tissue described by Rizack[6]; and an ability of this tissue to utilize 'non-active' glycerol in the esterification process possibly through a specific 'glycerokinase'.

Accordingly, lipase activity was determined in the epididymal fat from eight obese–hyperglycæmic mice and nine non-obese litter-mates obtained from the Jackson Memorial Laboratory in Bar Harbor, Maine. The animals were approximately four months old and fed Ralston Purina rat chow *ad libitum* until the time of death. Rizack's method for the estimation of lipase activity[6] was used with the exception that the total tissue homogenate (after removal of the fat cake) was used for the determination of enzyme activity. In the second series of experiments, six obese–hyperglycæmic mice and five non-obese litter-mates (all male) about 4 months old were used. Epididymal fat pads were incubated in Krebs-bicarbonate buffer. Glycerol-1,3-^{14}C was obtained from New England Nuclear Corporation and was added to the medium at a level of 2 μc. per flask (containing 3 ml. medium). Unlabelled glycerol was added to bring the total concentration of glycerol to 3 mM/l. In order to provide optimal conditions for tissue fatty acid synthesis, 5 mM glucose and 30 mM acetate were also added to the medium. Acetate was added as sodium salt in substitution for sodium chloride[4]. Incubation of the adipose tissue was carried out as described by Winegrad and Renold[7]. Tissue glyceride-glycerol was isolated according to Cahill *et al.*[8], oxidized with periodic acid, buffered and dimedone reagent was added to precipitate the formaldehyde derived from the α-carbons of glycerol as formaldimedone. The formaldimedone was washed, purified by recrystallization from acetone, washed twice, plancheted, counted and calculated[9].

Activity of the lipolytic enzyme system which appears to be responsible for the release of free fatty acids is significantly decreased in the adipose tissue from obese–hyperglycæmic mice (10·50 ± 0·92 μmoles free fatty acids/mg tissue nitrogen/1 h incubation) as compared with that of non-obese litter-mates (14·29 ± 1·69, $P < 0·02$).

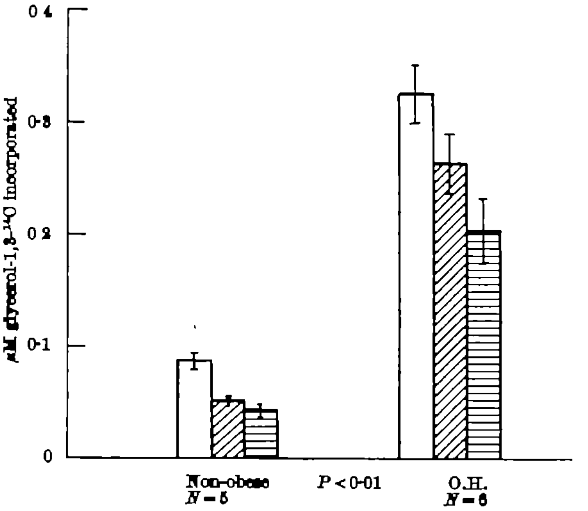

Fig. 1. Incorporation of glycerol-1,3-^{14}C into adipose tissue glyceride-glycerol of obese–hyperglycæmic mice (O.H.) and non-obese litter-mates. Results are expressed in micromoles labelled glycerol incorporated per mg tissue nitrogen per 3 h of incubation, mean ± *S.E.* It is readily seen that incorporation by adipose tissue from obese mice with this syndrome proceeds at 4–5 times the rate observed in tissue from non-obese litter-mates. White, control; oblique hatching, insulin 0·1 U/ml.; horizontal hatching, epinephrine 10^{-4} M

Incorporation of glycerol-1,3-^{14}C into glyceride-glycerol in adipose tissue of obese–hyperglycæmic and non-obese mice is shown in Fig. 1. When no hormone was added to the incubation medium, the incorporation of labelled glycerol into glyceride-glycerol by the adipose tissue from the obese–hyperglycæmic mice was three and a half times greater than that by the adipose tissue from the non-obese mice (0·33 ± 0·026 μmole/mg tissue nitrogen/3 h incubation in the obese–hyperglycæmic mice, 0·089 ± 0·007 in the non-obese mice). On addition of insulin or epinephrine to the incubation medium, the ratio of the rate of incorporation of glycerol-1,3-^{14}C in the adipose tissue from the obese–hyperglycæmic mice to that in tissue from the non-obese mice rose to 5 (0·27 ± 0·026 μmole for tissue from obese mice, 0·05 ± 0·004 μmole for tissue from non-obese mice in the presence of insulin; 0·20 ± 0·029 and 0·045 ± 0·003 μmole for adipose tissue from the obese–hyperglycæmic and non-obese mice, respectively, in the presence of epinephrine).

These results strongly suggest the existence of a glycerokinase in the adipose tissue of mice with the hereditary obese–hyperglycæmic syndrome, even though it is recognized that part of the apparent increase in labelled glycerol incorporated could be due to decreased dilution with the lesser amount of glycerol synthesized from glucose in this syndrome. Experiments now in progress should make it possible to rule out definitely this complication.

Proton Magnetic Resonance Investigation of Enzyme–Coenzyme Complexes

THE unique potentialities of high resolution nuclear magnetic resonance as a method for obtaining detailed information on molecular structure and molecular interactions in solution are well recognized[1,2]. However, the applicability of the method to the examination of interactions in biological systems has been hampered by its low sensitivity, requiring the use of comparatively concentrated solutions (~ 0·05 M or higher).

We have now applied a technique which has allowed us to perform a series of crude but informative experiments on the binding of diphosphopyridine nucleotide (DPN) to the enzyme yeast alcohol dehydrogenase (ADH) in stoichiometric proportions. Our procedure has been to couple the output of a Varian model 4300*B* high-resolution spectrometer operating at 60 Mc/s to a 400 channel digital average response computer, the Mnemotron model 400 computer of average transients. The sweep of the computer was triggered through a Tektronix model 535 *A* oscilloscope from a marker placed in the sample tube. By an appropriate choice of delay times, calculated from the known chemical shifts of the marker and the DPN peaks, it was synchronized with the desired linear portion of the field sweep, with excellent reproducibility on successive sweeps. The sweep rates found adequate in the present work were of the order of 2·5 mG/sec and the total field change in the course of a single computer sweep was approximately 25–30 mG, corresponding to a spectral region of 100–120 c/s. At this rate the spectrum was converted into digital form using 4 channels per c/s. Since the DPN peaks have a width at half-height of the order of 3 c/s, the resulting resolution was as good as that obtained on a conventional spectrum at higher DPN concentrations. Approximately 500 sweeps were required to obtain a well-defined spectrum of a dilute solution of DPN.

Figs. 1 *a* and *b* show the nuclear magnetic spectrum of 0·1 M DPN in deuterium oxide, *p*H 7·2, and the average response nuclear magnetic resonance spectrum of 0·002 M DPN in deuterium oxide, *p*H 7·2 (on an expanded scale). The assignment of peaks in the aromatic region follows from the spin–spin coupling pattern and is consistent with that given for other pyridine and purine derivatives[3-5]. A comparison of line widths to the coupling constants on the two spectra indicates that errors which could be expected to arise from sweep broadening and random drifts between successive sweeps are of the order of 10–20 per cent of the line widths.

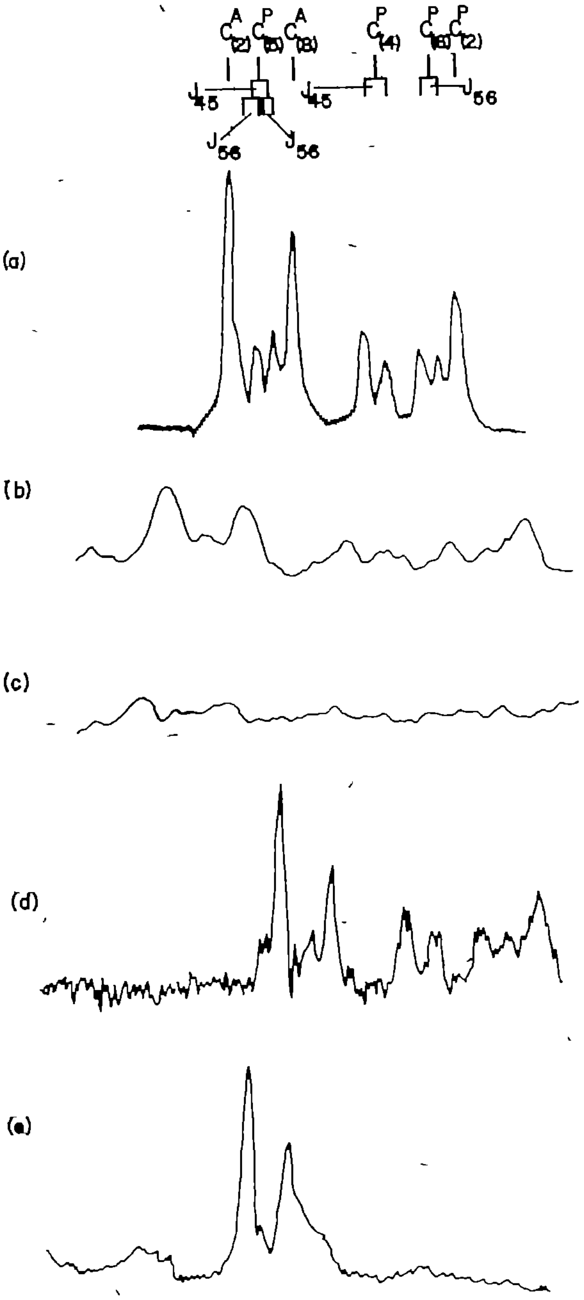

Fig. 1

The spectrum of 0·002 M β-DPN in the presence of 0·0005 M ADH, *p*H 7·2 (calculated on the basis of a molecular weight of 148,000 and a stoichiometric ratio for binding of 4 DPN molecules/molecule of ADH[6]) is shown in Fig. 1 *c*. The two adenine peaks can still be reproducibly detected, while the pyridine region of the spectrum gives random patterns on repeated scans. This would not have been expected in the case of a simple non-specific broadening, since the ratio of intensities of the C_2H of pyridine to the C_2H of adenine should have remained approximately 1 : 1 as it is in the case of the controls[1,2]. The same observation can be made more clearly on a solution containing a slight excess of DPN, as is shown in Figs. 1 *d* and *e*, which represent spectra of a control solution of 0·005 M β-DPN and the spectrum of 0·005 M β-DPN in the presence of 0·0005 M ADH. Whether this disappearance of the pyridine portion of the nuclear magnetic resonance spectrum represents a shift, selective broadening, or a combination of both, cannot yet be settled with certainty.

A scan of other regions of the average response nuclear magnetic resonance spectrum has thus far failed to reveal either these peaks, or the characteristic pyridine peaks of DPNH[7,8]. We therefore tentatively favour selective broadening (with or without an accompanying shift) as the more likely explanation. The possibility of the broadening being due to a difference in pH between the control and the enzyme-containing samples was carefully eliminated, since a pH dependent preferential broadening of the pyridine peaks has been observed above pH 8·5 and attributed to an exchange between the uncharged and the cationic form of the ring[9]. The possibility of a reduction of DPN to DPNH cannot be entirely excluded, but is made unlikely both by the absence of a substrate and by the failure to find the $H_{(2)}$ and the $H_{(4)}$ peaks of the dihydropyridine ring.

The fact that the spectral changes in the pyridine region are observable even when DPN is present in excess (10 molecules of DPN/molecule of ADH) suggests either binding of additional molecules through the pyridine ring or an exchange between the free and the bound species. Data available thus far do not allow a distinction between the two possibilities.

A precise interpretation of the present findings in terms of molecular events must therefore be deferred until the completion of a more detailed study at present in progress. However, regardless of the ultimate specific explanation, the observations made so far provide direct physical evidence for the involvement of the pyridine ring in the interaction between DPN and the enzyme, and provide a basis for defining the role of individual portions of the DPN molecule in this interaction. They also unequivocally demonstrate the feasibility of extending the application of nuclear resonance to the study of specific molecular interactions at biochemically meaningful concentrations.

Adenosine Triphosphatase Activity of Glycerinated Muscle Fibres in a Mechanical Field

MUSCLE is a 'mechano-chemical' system which can convert chemical energy into mechanical energy. The glycerinated muscle fibre is a typical example of the model system where the mechanical work (contraction) is closely coupled with the chemical reaction (dephosphorylation of adenosine triphosphate (ATP)). In such a mechano-chemical system, it is expected that the chemical reaction is also closely coupled with the mechanical work which is applied to the system.

Using the glycerinated muscle fibre, such a mechano-chemical coupling is studied, and it is observed that the ATP-ase activity of the muscle fibre is markedly accelerated under mechanical field.

Glycerinated psoas muscle fibres of rabbits were prepared by the method of Szent-Gyorgyi[1]. Seven fibre bundles (each 0·05–0·1 mm in diameter, 30 mm in length) are mounted between two levers which can stretch a fibre with various frequency and various amplitude. After washing the fibre with a medium (0·15 M potassium chloride and 0·002 M magnesium chloride buffered at pH 7·0), the reaction is started by immersing the fibre into 10 ml. of the same medium containing 2 mM ATP. The solution is continuously stirred and the temperature is kept constant by thermo-electronic elements[2] (Komatsu Electronics Inc., Tokyo). An aliquot of 0·5 ml. of the medium is taken out at the proper intervals and an inorganic phosphate liberated is assayed by the Hexanol–Celite column method[3].

When the lever is fixed, a steady rate of dephosphorylation is observed after an initial burst of dephosphorylation[4]. If the fibre is repeatedly stretched by the lever (frequency: 1·5 c/s, amplitude: 2 mm), the rate is immediately increased as shown in Fig. 1. This acceleration disappears when the movement of the lever is stopped, and the dephosphorylation rate returns to that of the original state.

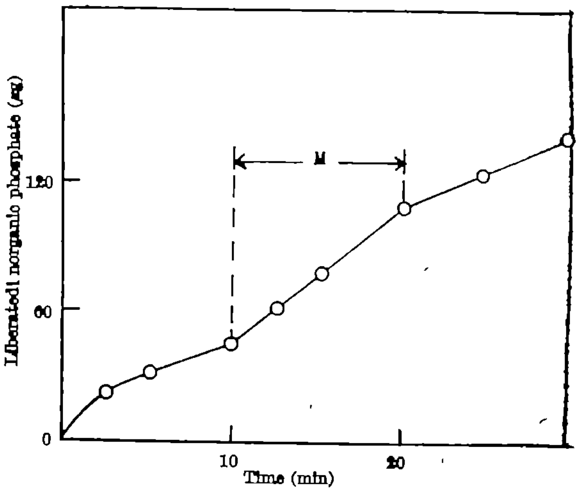

Fig. 1. Effect of repeated stretching on the dephosphorylation of ATP. Glycerinated muscle fibres (seven bundles, each 0·05–0·1 mm diam., 30 mm long) were immersed in 0·15 M potassium chloride, 0·002 M magnesium chloride, pH 7·0, and 0·002 M ATP. Temp., 20° C. *M* indicates repeated stretching (frequency, 1·5 c/s; amplitude, 2 mm)

The mechanical acceleration of the ATPase is also observed in muscle fibres under sonic vibration field just as observed in *F*-actin solution by Asakura[5]. When myofibrils prepared from the glycerinated muscle fibre (or rabbit muscle fibre) were put in the sonic field of a magneto-strictive sonic oscillator (frequency: 10 kc/s; input power of the final amplifier of the generator is about 15 W), the ATPase activity is accelerated (Fig. 2).

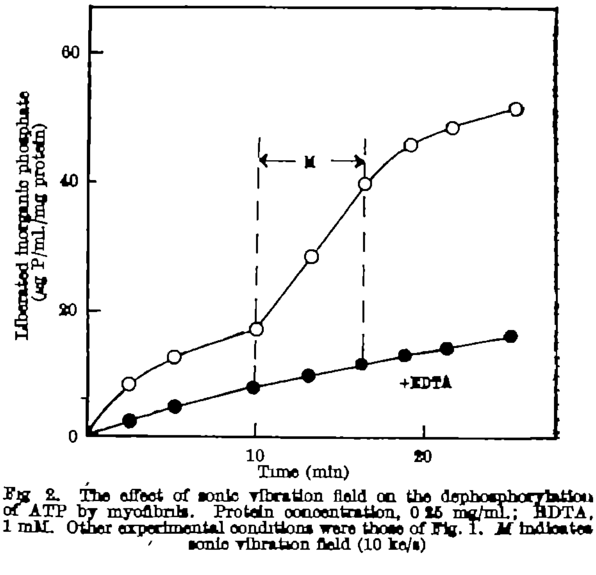

Fig. 2. The effect of sonic vibration field on the dephosphorylation of ATP by myofibrils. Protein concentration, 0·25 mg/ml.; EDTA, 1 mM. Other experimental conditions were those of Fig. 1. *M* indicates sonic vibration field (10 kc/s)

In the presence of EDTA (muscle-relaxing reagent), the ATPase activity of the myofibrils is suppressed and the mechanical acceleration disappears. The accelerated ATPase activities in Figs. 1 and 2 are nearly equal to the ATPase activity at the initial contraction process (initial burst). Therefore, it is probable that the interaction between myosin and actin filaments at the contracted steady state is enhanced by the mechanical work and that the ATPase activity is accelerated to the level at the initial contraction process.

We thank Prof. F. Oosawa for his useful discussions.

PHYSIOLOGY

Measurements of Tubular Fluid pH *in vivo* in Rats

IN recently reported micropuncture experiments on the mechanism of urine acidification in the rat, *p*H of tubular fluid was measured after the fluid had been withdrawn from the nephron[1–4]. A theoretical objection to this method is that carbonic acid may not be in equilibrium with carbon dioxide in the tubular lumen[5,6]. Withdrawal of the fluid would allow the reaction $CO_2+H_2O \rightleftharpoons H_2CO_3$ to reach equilibrium quickly with the result that both the concentration of carbonic acid and the *p*H would change. That this may be the case is suggested by recent estimates of tubular fluid *p*H *in vivo* by Rector, using a series of indicator dyes[7]. His results suggest a much greater degree of acidification in the proximal tubule than previously thought from *in vitro* measurements.

In the experiments reported here, a new method devised in this laboratory was used to obtain direct measurements of tubular fluid *p*H in the lumen without disturbing the physiological state of the nephron. Two micropipettes were inserted into the same tubular lumen along its longitudinal axis. One of the micropipettes contained a quinhydrone electrode and the other a silver–silver chloride reference electrode. Liquid junction was made via Ringer's solution. Tubular fluid was withdrawn under anaerobic conditions into the micropipette containing the quinhydrone electrode and *p*H measured as soon as electrical contact with the electrode was made. Then, this pipette was withdrawn from the lumen, the tip sealed with potassium chloride-agar, and *p*H determined *in vitro* at 37° C with a calomel reference electrode. The results are shown in Table 1.

	5·25	6·06	7·40	5·37

* In these experiments, carbonic anhydrase was administered intravenously; 6·4 mg was given as prime and 0·13 mg/min in the sodium sulphate infusion. Assay of bladder urine by the method of Philpot and Philpot (ref. 8) showed the enzyme to be present.

These results confirm the findings of Rector that tubular fluid *p*H *in vivo* is much more acid than plasma and considerably more acid than *in vitro*. The fact that *p*H rose after the fluid had been withdrawn from the nephron is most readily explained by a fall in the concentration of carbonic acid. This in turn is compatible with the view that carbonic acid is in a state of disequilibrium in the tubular lumen.

Two hypotheses, diametrically opposed to one another, to account for acidification of the urine are at present being held[5,6]. One proposes that bicarbonate ions are removed from the tubular fluid by a specific transport process, and the other that hydrogen ions are secreted by the epithelial cells. Either of these two mechanisms is compatible with the low *in vivo p*H values found in the experiments reported here. However, the fact that *p*H rose after the fluid had been withdrawn from the nephron favours the hydrogen ion secretion theory. If bicarbonate removal were the primary event, the reactions taking place in the tubular lumen would be:

$$(1)\ H_2CO_3 \rightarrow H^+ + HCO_3^-$$

$$(2)\ CO_2 + H_2O \rightarrow H_2CO_3$$

The concentration of carbonic acid might be expected to rise, therefore, after the fluid had been withdrawn from the nephron if the hydration of carbon dioxide (equation 2) had not reached equilibrium *in vivo*. The *p*H measured *in vitro* would be more acid in these circumstances than *in vivo*. In contrast, if hydrogen ion secretion is the basic mechanism, reactions 1 and 2 would be proceeding toward the left in the tubular lumen as hydrogen ions combined with bicarbonate to form carbonic acid. Removal of the fluid from the nephron would allow the dehydration of carbonic acid to continue to equilibrium with the result that carbonic acid concentration would fall and *in vitro p*H would be higher than *in vivo*.

It is of interest that carbonic anhydrase, in amounts large enough to cause its excretion in the urine, was unable to accelerate the dehydration of carbonic acid sufficiently for equilibrium to be reached *in vivo*. Larger amounts might have been more effective, but it is also conceivable that factors other than presence or absence of this enzyme, such as the rate of hydrogen ion secretion, the geometrical relationship between luminal surface area and fluid volume, and the rate of flow along the nephron preclude a state of equilibrium for carbonic acid.

The concentration of carbonic acid in the tubular lumen can be approximated from the equation: $pH = 3{\cdot}2 + \log HCO_3^-/H_2CO_3$. At a *p*H of 5·5 and a bicarbonate concentration of 25 mm/l. carbonic acid would be 0·1 mm/l. or almost 100 times that of plasma. At the same *p*H but lower bicarbonate concentrations, carbonic acid concentration would be proportionally smaller. This could account for the fact that *in vivo* and *in vitro p*H were much closer to one another in the case of distal tubular samples than with proximal samples. If most bicarbonate is reabsorbed in the proximal tubule and little reaches the distal tubule, relatively small amounts of carbonic acid would be generated distally and the dehydration reaction could more easily approach equilibrium *in vivo*.

In previous experiments reported from this laboratory[4], a correlation was made between proximal tubular fluid *p*H measured *in vitro* and trans-tubular electrical potentials, using the simplified Nernst equation: $Em = 61{\cdot}5 \log C_1/C_2$. The results suggested that hydrogen ions are distributed passively between proximal fluid and plasma in response to the electrical potential. On the basis of the present findings, however, it seems certain that an active transport mechanism for hydrogen ions must be in operation since the highest recorded proximal electrical potentials can account for H+ gradients of less than 1 *p*H unit.

Vitamin B_{12} in the Serum of the Rhesus Monkey

MOST investigations of the physiology of vitamin B_{12} have been carried out in man or laboratory animals other than the sub-human primates. Indeed, it has been specifically noted that vitamin B_{12} deficiency has not been produced experimentally in monkeys[1-3], and those macrocytic anæmias which have been induced are known to respond to treatment with folic acid (sometimes in association with ascorbic acid) but not to vitamin B_{12} (ref. 4).

Recently, two rhesus monkeys in our colony developed a paralysis which called to mind sub-acute combined degeneration of the cord in man and which improved following treatment with parenteral vitamin B_{12}. This led us to measure the serum-levels of the vitamin in other monkeys in the colony. Using the microbiological assay method with *Euglena gracilis*[5], the level of vitamin B_{12} was estimated in the sera of three male and 18 female normal untreated adult rhesus monkeys (*Macaca mulatta*) which had been in the colony for 1–15 years. The mean figure of 56·6 $\mu\mu$g/ml. (*S.D.* 20·8) is very low compared with the levels found in other mammals (not less than 200 $\mu\mu$g/ml. by the same technique[6]), and with the range of normal in man (mean value 390 $\mu\mu$g/ml.[5]); in fact, it is the value to be expected in cases of pernicious anæmia in relapse.

Low levels similar to those which we have found have already been observed by Wilson and Pitney[7] in 17 young rhesus monkeys which had been on a standard laboratory diet for many months. The mean serum-level of 120 $\mu\mu$g/ml. was accepted by them as normal for the species. Das Gupta *et al.*[8] found even lower levels in six healthy young rhesus monkeys (mean value 56·8 $\mu\mu$g/ml.) living on the "usual animal room diet", and they commented that the somewhat higher figures obtained by Wilson and Pitney[7] might have been due to the higher vitamin B_{12} content of their 'natural' laboratory diet.

Repetitions of the tests on our monkeys have shown that the levels of vitamin B_{12} remain consistently low. On the other hand, monkeys that have been in the laboratory environment for only a short period showed higher levels at the time of the first test, but the values fell to the low figure characteristic of the rest of the colony within three months. Estimates on a group of 29 monkeys examined within five weeks of captivity and immediately on arrival in Britain gave a mean value of 208·2 $\mu\mu$g/ml. (*S.D.* 93·2). These findings imply that monkeys in their natural habitat have satisfactory amounts of vitamin B_{12} in their serum as judged by the standards of man and other mammals, perhaps as the result of a more varied diet in the wild state.

The ordinary diet fed to our monkeys consists of potatoes, bread, carrots and other root vegetables, green vegetables and fresh fruit, and is supplemented with 'Bemax', ascorbic acid and halibut liver oil. This diet has been thought to be adequate since monkeys have been kept on it in apparently good health for long periods of time—up to 24 years—and since hæmatological examinations have never revealed any notable changes. Further examinations of the blood from these monkeys now known to have low vitamin B_{12}-levels have also failed to show any significant evidence of anæmia.

This overall picture of very low levels of serum vitamin B_{12}, usually without obvious signs or symptoms of deficiency, in monkeys on a vegetarian diet seems closely to resemble the findings in strict vegetarians[9,10], where low serum B_{12} values are not necessarily associated with anæmia or gross neurological changes. In many other species, however, there is evidence that vitamin B_{12} deficiency may lead to a range of disorders including retardation of growth, congenital deformity, increased incidence of demyelinating disease of the nervous system and a number of lesser effects (for review see ref. 2). Special mention may also be made of the many reports that the deficiency has some ill-defined influence on the reproductive processes[11-14]. We intend particularly to study the influence of vitamin B_{12} supplements in our group of breeding females the fertility of which has proved to be disappointingly low, and would suggest that other users of laboratory primates might consider the possible effect of low levels of vitamin B_{12} in the serum in the interpretation of their results.

Serum Iron in Normal and Castrated Mammals

MOST authors are agreed that there is a sexual difference in serum iron values in man.

Previous work[1,2] carried out on six kinds of mammals has not, however, shown this difference. On the other hand, it seems beyond doubt that the gonads have a definite effect on iron metabolism in some species. The castration of rats[3] and rabbits[4] modifies the level of serum iron and in the former affects hepatical deposit[5].

The injection of sex hormones has also a certain influence on other species, and it has been seen how the œstrogens reduce the serum iron in rats[4] and in rabbits[6].

In the work recorded here, I have examined the influence of gonads on the serum iron values and the total iron-binding capacity in 5 species of mammals—bull, horse, ass, lamb and pig. For this purpose the values for normal and castrated specimens are compared. The results obtained with the first three species have already been given[7].

The serum iron values and the total iron-binding capacity are determined using Ramsay's methods[8,9]. The average values of both the normal and castrated specimens have been submitted to a test of statistical significance (Student's *t*).

Table 1. AVERAGE VALUES FOR SERUM IRON AND TOTAL IRON-BINDING CAPACITY (TIBC) FOR THE SPECIES CONCERNED

The results given in Table 1 shows that in the species studied no clear influence of castration on the serum iron values is noted. In general a decrease in values can be observed, but the differences which appear are not statistically significant. An evident decrease in serum iron following castration has been quoted in the horse[10], but the average of only 5 specimens was taken. With respect to the values of the total iron-binding capacity we have only found a significant difference existing in the bovine species ($t = 2{,}181$), being lower in castrated than in the normal types.

The effect of castration on serum iron values does not seem to be uniform in the different mammals referred to, and for the moment every attempt to generalize the action of sexual hormones on iron metabolism should be treated with reserve.

The opinion of certain authors[11] that it is difficult to obtain an explanation of the sexual difference in man from the endocrinous effects found in other mammals now appears to me more justified than ever.

HÆMATOLOGY

Types of Haptoglobins in Araucanian Indians of Chile

SINCE the discovery of the polymorphism among haptoglobins in human serum made by Smithies[1] with starch-gel electrophoresis, information concerning geographical distribution has increased rapidly.

The Hp 1 gene is known to be common in Africa, but rare in Asia, especially India. In Europe, from east to west Hp 1 increases slowly. In America, Sutton[2] has noticed an increase from Mongolian and Amerindian population from south-east Asia (0·22 in the Japanese), through Alaska (0·33) and North America (0·45 in Navajos and 0·59 in Apaches) to Central (0·59 in the Mayas) and South America. In the last-named area the values are: Venezuelan Indians (0·55) and Peruvian Indians (0·73). A limited series of 34 Mapuche Indians from Temuco has been reported by Parker and Bearn[3] finding 0·74.

Serum specimens were obtained from 229 'full blooded' Araucanian Indians of the south of Chile: 113 of the Pehuenche sub-group and 116 of the Mapuche sub-type. They speak the same language, but their habitat and customs are quite different. The Pehuenches examined live in Lonquimay, in a hidden valley of the Andes; they are very isolated and originally were nomads. Their admixture with white is very low, as can be seen from their blood groups (Table 1)[4]. The population is rather scanty and very endogamic. A very high incidence of goitre exists in this region[5].

Table 1. CLASSIC BLOOD GROUPS OF ARAUCANIAN INDIANS OF CHILE

	Total individuals	O	A	B	AB
Mapuches (Temuco)	450	358 (79·6)	50 (11·1)	42 (9·3)	0 (0)
Pehuenches (Lonquimay)	182	174 (95·6)	6 (3·4)	2 (1·1)	0 (0)

Percentages in parentheses.

The Mapuche Indians examined were from the Central Valley of Chile, near Temuco. This population constitutes the main group of the Araucanian Indians. They are classified as an agricultural and sedentary population since the pre-Columbian period. Their proximity with white cities has elevated admixture to 30 per cent more or less, an estimation based on their blood groups. These findings are consistent with earlier surveys made in the same region in relation to blood groups[6].

The Negro admixture of the two groups must be very low, if any. Neither glucose-6-phosphate dehydrogenase deficiency nor abnormal hæmoglobins were found[4].

Serum was separated the same day, and stored at 20° C for 20–60 days when starch-gel electrophoretical analysis was performed in a vertical set, with borate buffer (*p*H 8·6), and stained half with amido black 10*B* and half with benzidine-peroxide reagent. Hæmoglobin was added to all samples except when they were obviously hæmolysed.

Table 2. HAPTOGLOBINS OF ARAUCANIAN INDIANS OF CHILE

		Haptoglobin types 1–1	2–1	2–2	Total individuals	*p*Hp 1	*S.E.*
(I) Pehuenches (Lonquimay)							
(*a*) Without goitre							
Unrelated		22	14	1	37		
Related	2	8	6	1	15		
	3	5	1	0	6		
	4	4	0	0	4		
					62	0·78	0·04
(*b*) With goitre							
Unrelated		25	14	0	39		
Related	2	4	3	1	8		
	4	3	1	0	4		
					51	0·80	0·04
					113	0·78	0·02
(II) Mapuches (Temuco)							
Unrelated		65	39	12	116	0·72	0·02

Table 2 shows the results with both Pehuenche and Mapuche groups. The Pehuenches are divided according to consanguinity and size of the family, and according to presence of goitre. The Mapuche were all unrelated and had no goitre. The differences among these two groups reflect the endogamic and endemic goitre characteristic of the first group. As the population examined was partially related, we calculated the gene frequency according to Cotterman's method[7].

The highest frequency of gene Hp 1 was found in Lonquimay, where we suspect a low admixture with white. In Temuco, instead, where the admixture is very high, the frequency falls. There are sufficient facts to suggest that all the Araucanian sub-types were very much related before the arrival of the Spaniards, so that subsequent admixture seems to be the best explanation for the differences found in the Hp 1 gene frequency. This suggests also that the primitive Araucanian Indians of the pre-Columbian period must have had an Hp 1 gene frequency of more than 0·80.

Our results are in very good agreement with what would be expected under Hardy–Weimberg equilibrium (*P* more than 0·30).

In summary, the Hp 1 frequency of the Araucanian Indians is reported as being 0·72 (*S.E.* 0·02) for the Mapuche and 0·78 (*S.E.* 0·02) for the Pehuenches, in accordance with the increase described from south-east Asia to South America. Endemic goitre does not seem to be related to this gene distribution.

We thank Dr. C. Guzmán, Dr. A. Hille, Dr. E. Covarrubias and Mr. A. Montenegro for their help as participants in the expedition, Dr. E. Giblett and W. C. Parker for providing reference serum and advice, and Dr. Danko Brncic and José Barzelatto for interesting discussions.

Inactivation of Thrombin by Normal Human Urine

CONTINUING our investigations of thrombin inactivation in blood and other body fluids[1–4], in order to determine their antithrombin activity, we decided to examine the influence of normal human urine on the activity of added thrombin.

(1) The standard thrombin solution is obtained by dissolving a small quantity of thrombin pulver ('Thrombofort' Richter) in physiological sodium chloride solution. By addition either of thrombin or physiological saline we fixed the activity of thrombin solution, that is, 0·1 ml. mixed with 0·1 ml. of physiological saline coagulated 0·2 ml. of standard dry plasma solution during 30 ± 2 sec. (2) The plasma substrate is prepared by dissolving the dry, lyophilized plasma (produced at the Blood Centre, Krakow, Nowa Huta) in distilled water in gravimetric proportion 7·5 : 100·0. This concentration corresponded to that used for intravenous infusions. (3) The urine is obtained from normal, fasting, healthy adults of both sexes. The urine is centrifuged (10 min, 3,000 r.p.m.) in order to eliminate the morphological elements. During further examination only the upper layer of centrifuged urine is used. We examined: reaction (whether acid, neutral, alkaline), specific gravity, colour, transparence, contents of proteins, sugar and a microscopic picture of sediment. A more exact determination of *p*H was made with universal indicator paper (Labo Moderne, Paris 1e), having a sensitivity of *p*H 0·1. The findings did not differ from normal values. We examined 35 specimens of urine with *p*H's of 5·0–10·0.

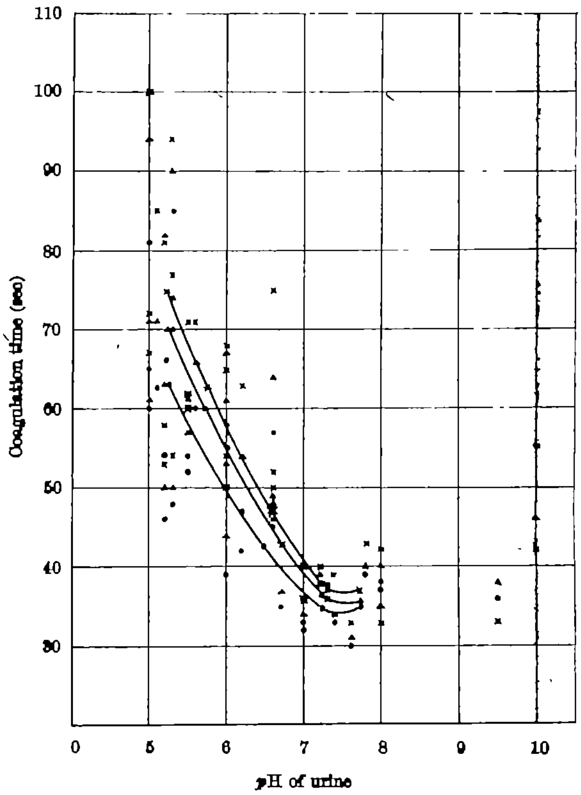

Fig. 1. ○, Values of coagulation time after 0-min. incubation; △, values of coagulation time after 10-min. incubation; ×, values of coagulation time after 20-min incubation. The figures are based on the mean values of coagulation times of the *p*H limits: 5·0–6·0, 6·0–7·0 and 7·0–8·0

To determine thrombin inactivation, 0·1 ml. of thrombin standard solution was mixed with 0·1 ml. of examined urine, and immediately after (10–15 sec) 0·2 ml. of plasma substrate was added and the coagulation time of the whole mixture determined. The same volumes of thrombin solution and urine were mixed and incubated in room temperature for 10 and 20 min. also. After that time 0·2 ml. of plasma substrate was added again and the time of coagulation determined. In the control reaction instead of 0·1 ml. of urine the same quantity of physiological saline was used. All results are given in seconds. These are presented in Fig. 1. It shows that when thrombin is mixed with urine the *p*H of which is less than 7·0 (acid urines) the time of coagulation becomes immediately prolonged as compared with its control values (0 min incubation). The degree of prolongation depends on *p*H; the nearer to its neutral value of 7·0, the lesser becomes the prolongation of coagulation time. Besides this relationship one can observe that the urines having the same value of *p*H do not prolong identically the coagulation time as compared with its control values.

When the urine is neutral or slightly alkaline and the *p*H equal to or higher than 7·0 the coagulation time undergoes only small or no prolongation. The strongly alkaline urines cause a moderate prolongation of the coagulation time.

The 10- and 20-min. incubation period of all urines prolongs little or not at all the values of times of coagulation in comparison with initial value (0 min incubation).

The influence of *p*H on the coagulation of blood and plasma and the thrombin activity is well known[4–6]. Various investigators find the optimal activity of thrombin at the *p*H 7·2–7·5; the maximal activity of thrombin appears at the neutral or slightly alkaline *p*H (7·0–8·0). The further from those values and the nearer to strongly acid or alkaline *p*H the weaker becomes the action of thrombin. Our results confirm those already published.

Schulz[10] investigated among other problems the influence of normal human urine, obtained in the morning from fasting individuals, on the coagulation time of recalcified, oxalated blood and plasma and did not find any action of urine on the recalcification time under the conditions of his experiments.

Conclusions. (1) Normal examples of human urine with acid or strongly alkaline pH inactivate immediately the added thrombin. The degree of inactivation depends in great part on the distance of urine pH from its neutral value. This inactivation is very small or none when the urine pH is neutral or slightly alkaline. The incubation of urine with thrombin increases little (or does not increase at all) the initial inactivation. (2) The results of *in vitro* investigations prove that the alkalization of urine obtained by appropriated diet or pharmacological remedies may *in vivo* exercise a favourable influence on threatening or already existing hæmorrhages of the urine-excreting system.

HISTOCHEMISTRY

Histochemical Demonstration of Aminopeptidase Activity in the Cells of the Blood and Bone Marrow from Various Hæmatological Disorders

Aminopeptidase activity has been demonstrated histochemically in the leucocytes of the blood and bone marrow of man using alanyl β-naphthylamide as the substrate[1,2]. Cytoplasmic aminopeptidase activity was localized in the neutrophils, monocytes and eosinophils while lymphocytes and basophils failed to exhibit a positive reaction for aminopeptidase activity[1]. During granulopoiesis, aminopeptidase activity appeared initially in the late *B* myelocytes and gradually increased during later stages of maturation; erythrocytic elements were non-reactive.

The procedure used in this investigation has been detailed by Ackerman[1] and entails the fixation of air-dried films with cold 0·5–1 per cent osmium tetroxide in dimethylformamide for 2 min, washing in running water and placing the films in an incubation medium containing 4 mg of alanyl β-naphthylamide dissolved in 5 ml. of distilled water, 5 ml. of 0·1 M Sorenson's phosphate buffer at pH 6·7, 1 mg of magnesium sulphate and 5 mg of fast garnet *GBC*. Incubation periods of 6–18 h at room temperature were used routinely. Following incubation the films were washed in running water, blotted dry and mounted in glycerine or glycerogel; counter-staining with 0·5 per cent aqueous methyl green was optional. Alanyl β-naphthylamide hydrochloride used as the substrate was synthesized in our laboratory using the method outlined by Burstone[3,4].

Blood and bone marrow films obtained from patients with various hæmatological disorders were processed with blood and/or bone marrow films from individuals exhibiting no hæmatological disfunction. Ninety-one patients with hæmatological dyscrasias were examined: chronic myelocytic leukæmia (12); acute–sub-acute myelocytic leukæmia (5); acute–sub-acute monocytic leukæmia (15); chronic lymphocytic leukæmia (16); leuco-lymphosarcoma (14); Hodgkin's disease (4); lymphoma (3); polycythæmia vera (3); secondary polycythæmia (2); thrombocytopenic purpura (5); pancytopenia (3); iron deficiency and hæmolytic anæmia (6) and infectious mononucleosis (3). The relative activity, judged by the intensity of the reaction, of the cellular elements in the hæmatological disorders were evaluated and compared with similar cells from the normal individual. The processing of normal films with abnormal blood and/or bone marrow films permitted an important controlling factor minimizing possible variations in the histochemical procedure.

In general, increased aminopeptidase activity was observed in the myelocytes and mature neutrophils in chronic myelocytic leukæmia as well as in the younger myelocytes in acute–sub-acute myelocytic leukæmia; myeloblasts and promyelocytes were non-reactive. The mature neutrophils exhibited relatively normal reactions for aminopeptidase in acute-sub-acute myelocytic leukæmia while the neutrophils and developing granulocytes from patients with chronic myelocytic leukæmia receiving antileukæmic therapy exhibited normal to slightly decreased aminopeptidase activity with the procedures used in this investigation. In acute–sub-acute monocytic leukæmia, the young and relatively mature monocytes usually exhibited increased aminopeptidase activity as compared with normal mature monocytes; monoblasts were non-reactive and the mature neutrophils exhibited an essentially normal aminopeptidase reaction. During the differentiation of the neutrophilic myelocytes and monocytes, aminopeptidase activity appeared initially in the region of the cytocentrum and became more generalized during maturation. Aminopeptidase activity was demonstrable only after the development of peroxidase activity in these cells.

Lymphocytic cells present in chronic lymphocytic leukæmia and lymphosarcoma were non-reactive, and the mature neutrophils and developing myelocytes present in the bone marrow of these individuals were normal in their histochemical reactivity. Normal reactions for aminopeptidase were observed in the neutrophils and myelocytes from individuals with polycythæmia, hæmolytic and iron-deficiency anæmias, thrombocytopenic purpura, pancytopenia, Hodgkin's disease, lymphoma and infectious mononucleosis. Increased aminopeptidase activity was noted in the neutrophils from patients with pyogenic infections.

No attempt was made to place the histochemical reactions for aminopeptidase activity observed in the cells of the blood and bone marrow on the same level of semi-quantitative evaluation as has been utilized in the study of leucocyte alkaline phosphatase activity since our experience indicated the capriciousness of the reaction and the not infrequent variation in cellular reactivity in different areas of the same preparation. In spite of these inherent difficulties, our investigations revealed what appear to be significant variations in leucocyte aminopeptidase activity in certain hæmatological disorders, for example, myelocytic and monocytic leukæmias and in pyogenic infections. Differences between aminopeptidase, alkaline phosphatase and peroxidase activities were evident and of interest. Although the present histochemical procedure for aminopeptidase activity may not assume a significant role in diagnosis of various hæmatological disorders, it does merit further study and adds to our knowledge concerning the histochemical alterations occurring in the cells of the blood and bone marrow in disease. Improvements and refinements in both the histochemical substrates and techniques can be expected to improve the sensitivity and reliability of methods for the histochemical determination of aminopeptidase activity.

Nuclear Deoxyribonucleic Acid Content in Corona Radiata of the Ovary of the Rat

THE mere situation of the corona radiata in the follicle is highly suggestive of the existence of inter-relationship between the granulosa and the oocyte. Experimental work revealed that the granulosa cells assume a role in transporting hormonal[1–4] and nutritional[5] substances towards the oocyte. Furthermore, morphological evidence of a pathway between both was given recently[4].

Numerous investigations, especially in endocrine organs, showed the DNA content of the nuclei to be closely related with cell function[6]. Since the variations of the DNA content of the components in the rat ovary were particularly marked[7–10], I tested whether the DNA content of the granulosa cells of the follicle wall would differ from that present in the corona radiata. For that purpose the DNA content in interphasic nuclei of both elements was determined by Lison's histophotometrical method[11] on Feulgen-stained ovaries of rats in procestrus and cestrus containing w ll-developed tertiary follicles. After fixation in a mixture of alcohol 75 per cent, formalin 20 per cent and acetic acid 5 per cent, the ovaries were treated under the usual standardized conditions[6].

The determinations of DNA were carried out in 9 tertiary follicles out of 3 series of ovaries. In each series the individual values were assembled in a pool (Table 1). In every case significant differences were noted between the corona radiata and the granulosa of the follicle wall: in the first series the DNA content of the periovocytary nuclei is 35 per cent ($P < 0·001$) higher than in the peripheral nuclei; in the second and third series the differences are, respectively, 30·5 ($P < 0·001$) and 24·9 ($P < 0·001$) per cent. This difference seems to be limited to tertiary follicles. No significant distinction in DNA content appeared between the granulosa cells surrounding the oocyte and those belonging to peripheral layers in secondary follicles without antrum formation (Table 2). The difference of 4·6 per cent falls within the limits of error.

In order to check possible gonadotropic influences, the work was extended to the hypophysectomized animal. Five days after hypophysectomy, the difference in DNA content between the nuclei of the corona radiata and the peripheral ones of the follicle wall in some well-preserved tertiary follicles was only 16 per cent and had no statistical significance ($0·2 < P < 0·3$) (Table 3). However, a significant difference seems to be restored after gonadotropic replacement. After daily administration of chorionic and serous gonadotropin to the hypophysectomized animal during 5 days the difference of the DNA content again attains, respectively, 35·9 ($P < 0·001$) and 34·7 ($P < 0·001$) per cent.

Table 1

Series II (*KR* 18–19–21)	Follicle wall	151	1,000	3·0000	0·093	0·0082
	Periovocytes	97	1,305	3·1156	0·106	0·0132
Series III (*KR* 111–115–123)	Follicle wall	146	1,000	3·0000	0·068	0·0077
	Periovocytes	54	1,249	3·0966	0·078	0·0107

Table 2

KR 19 and *KR* 21	n	$\bar{x}$	$\log \bar{x}$	s	$s_{\log \bar{x}}$
Peripheral	67	1,000	3·0000	0·133	0·0142
Periovocytes	29	954	2·9797	0·106	0·0097

Table 3

		n	$\bar{x}$	$\log \bar{x}$	s	$s_{\log \bar{x}}$
Hypophysectomy	Follicle wall	203	1,000	3·0000	0·088	0·0062
	Periovocytes	46	1,163	3·0656	0·311	0·0046
Hypophysectomy + chorionic gonadotropin	Follicle wall	199	1,000	3·0000	0·085	0·0079
	Periovocytes	49	1,359	3·1332	0·112	0·0123
Hypophysectomy + serous gonadotropin	Follicle wall	152	1,000	3·0000	0·085	0·0069
	Periovocytes	65	1,347	3·1293	0·121	0·0150

By means of the histophotometrical determination of nuclear DNA in the granulosa cells of cavitary follicles in the rat, a fair distinction can be made between the cells of the follicle wall and the corona radiata. This finding argues in favour of a functional distinction between these follicular components. This distinction, which is probably related with the special transfer functions of the corona radiata, seems to depend on gonadotropic influences.

Soluble Glucokinase Activity in Bovine Tissues

PREVIOUS investigations of glucokinase activity in ruminant tissues have involved the measurement of glucose or oxygen uptake (in the presence of glucose as substrate) by tissue homogenates, mitochondria or supernatants after centrifugation of homogenates at 9,000*g* [1–3]. These methods showed glucokinase activity in brain and intestinal mucosa, but not in the liver of sheep. The apparent lack of glucokinase activity in the liver preparations may have been due to the presence of powerful glucose-6-phosphatase activity[4]. The interfering enzyme can be removed by centrifugation of homogenates at 100,000*g*, and this step has revealed appreciable activity of soluble glucokinase in rat liver[5], which was previously thought to have only slight glucokinase activity. This technical development suggested that glucokinase activity in ruminant tissues should be re-evaluated, for it is of interest in at least two respects. First, from the comparative view, overall glucose utilization is less in intact ruminants than in other mammals[6], so low glucokinase activities may be expected in some tissues. Secondly, some metabolic diseases, such as pregnancy toxæmia in sheep and acetonæmia in cows, resemble diabetes in some regards, and the hepatic glucokinase activity of fasting or alloxan-diabetic rats is only about 40 per cent that of normal, fed rats[5].

The present method was based on those of DiPietro and Weinhouse[5] and Grignani and Lohr[7]. Tissues were taken from seven adult cows at a slaughter-house within 10 min after stunning, and from five adult female rats which had been fasted overnight. Homogenates were prepared by disintegrating 1 g of tissue in 10 ml. of ice-cold buffer (0·15 M potassium chloride, 5 mM sodium ethylenediamine tetraacetate, 5 mM magnesium chloride, *p*H 7·0) in a Waring blender. Supernatants were obtained by centrifuging the homogenates at 100,000*g* for 30 min in a Beckman/Spinco model *L* centrifuge.

Assay of the soluble glucokinase involved measurement of the rate of increase of optical density at 340 mμ of a reaction mixture in a Beckman *DU* spectrophotometer. It depended on the generation of reduced nicotinamide-adeninedinucleotide-phosphate (NADPH) in the presence of added glucose-6-phosphate dehydrogenase. Final concentrations in the reaction mixture were 50 mM glycylglycine at *p*H 7·6, 8 mM magnesium chloride, 1 mM sodium fluoride, 0·75 mM adenosine triphosphate (ATP) except in the blanks, 0·25 mM NADP, 2 mM EDTA, and in addition each cell contained at least 0·02 Kornberg units of glucose-6-phosphate dehydrogenase (Sigma Chemical Co., St. Louis, Mo.). The final volume was 2·1 ml., and up to 0·3 ml. of supernatant could be included. The reaction was started by the addition of ATP except in the blanks. Increase in optical density was linear for at least 10 min. Micromoles of NADPH generated were calculated from a molar extinction coefficient of 6·22 × 10⁶ cm²/mole.

The results are shown in Table 1. All tissues tested had soluble glucokinase activity. In bovine tissues, the activity was high in salivary gland, mammary gland and duodenum, moderate in brain, liver and kidney, and low in muscle and adipose. Glucokinase activity in rat tissues were 2·3 to 6·3 times higher than in corresponding bovine tissues.

Table 1. SOLUBLE GLUCOKINASE ACTIVITY*

Tissue	Cows, 7	Rats, 7
Salivary gland	30·7 ± 4·8†	—
Mammary gland	36·0 ± 2·2	—
Duodenum	36·2 ± 2·3	81·0 ± 13·5
Brain	28·4 ± 3·3	139·6 ± 9·3
Kidney	25·2 ± 2·2	100·4 ± 9·3
Liver	17·4 ± 1·3	44·7 ± 4·5
Muscle	8·6 ± 0·8	34·2 ± 6·1
Adipose	3·1 ± 0·3	19·5 ± 2·8

* One unit represents the formation of 0·01 μmole NADPH/min/g fresh tissue under the conditions described in the text.
† *S.E.*

The comparative significance of these results is difficult to assess because of the problem of body-size. If a relation to the three-fourths power of body-weight which holds for oxygen consumption of intact animals[8] applies here also, the rat tissues should have about 7 times the glucokinase activity of the cow tissues. Since this is approached only in the case of adipose tissue, it seems that the generalization does not apply. Krebs[9] has found this also to be the case for oxygen consumption of tissues *in vitro*. At present, we can only note that the ruminant glucokinase activities are less than those of the rat, without deciding on the relative influence of body-size and of different patterns of metabolism.

The results do tell us something, however, about the pattern of ruminant glucose metabolism. The tissues which appear to utilize little glucose are skeletal muscle and adipose. Reid[10] has suggested that acetate uptake spares the utilization of plasma glucose by muscle in sheep. Acetate might also be taken up by the adipose tissue and be synthesized into fatty acids in a way similar to mammary lipogenesis in the cow. The uptake of plasma glucose by the mammary gland and its utilization for synthesis of lactose and glycerol are well known[11]; but we have found no information on glucose metabolism by salivary gland. The high activity of duodenal glucokinase is provocative, since the glucose-6-phosphatase activity is low[4]. Perhaps glucose taken up by intestinal mucosal cells is transformed during the process of absorption. The presence of soluble hepatic glucokinase supports the suspicion that the deficiency of glucokinase activity found by Gallagher and Buttery[3] was due to glucose-6-phosphatase activity in their preparations[1,3]. Further work is in progress on tissues from normal sheep, and from cases of pregnancy toxæmia and acetonæmia.

Thermal Injuries and Formation of Mucopolysaccharides in the Skin

WE have recently demonstrated that in tuberculous tissue[1], in carcinoma[2], in varicose ulcer[3] and in silicotic tissue[4] large amounts of a periodic acid–Schiff-positive material are found which—according to different histochemical and chemical control examinations—in all probability correspond to neutral mucopolysaccharides[5]. Further examinations disclosed that under physiological and pathological conditions the thyroid gland has an important role in the regulation of the mucopolysaccharide contents of the organism[6–7]. It is probable that the mucopolysaccharide metabolism of a tissue *in situ* is dependent on its vascular supply. As a consequence of a poor blood supply a state of hypoxia or anoxia ensues and oxybiosis must give place to a more primitive kind of metabolism which will then ensure for a certain time the energy supply of the damaged tissues. In the course of this new metabolism, neutral mucopolysaccharides arise as metabolic derivatives[8]. Neutral mucopolysaccharides are produced in tissues whenever a stage of hypoxia or anoxia sets in in the tissues, but the degree of the histological damage is not so severe as to involve the immediate destruction of the entire tissue.

Knowing that injuries of the skin caused by burning or freezing lead to hypoxia or anoxia, we carried out experiments to determine the alteration of the metabolism with special regard to the formation of neutral mucopolysaccharides.

Our experiments were performed on 15 guinea pigs and 10 rats. The skin of the guinea pigs was burned or frozen under general anæsthesia. The rats were submitted to scalding (4 sec). Freezing was carried out by applying dry ice (120 sec). The effect of time factor of the injuries was studied on specimens of skin examined daily from animals of each series, for a period of a week.

The histological preparations were stained by Ritter–Oleson's, hæmatoxylin–eosin, and Van Gieson's method. The staining of Ritter–Oleson was supplemented by enzyme digestion, acetylation and studies of metachromasia. In rats determinations of serum hexosamine were also made.

Our experimental results seem to give strong support to our presumption that in injuries of the skin caused by burning or freezing, especially in the vesicles and in the cutis, large quantities of periodic acid–Schiff-positive material arise which in all probability correspond to neutral mucopolysaccharides. Shortly following the injury, increase of acid mucopolysaccharides may be observed, but beginning with the second or third day following the injury, the local appearance and the increase of neutral mucopolysaccharides are striking. The hexosamine content of the blood was found also to double shortly after the injury and slowly decrease from the third or fourth day following the injury.

We think that our results add support to our statement that the histological appearance *in situ* of neutral mucopolysaccharides is the consequence of a metabolic process following a general biological rule—a process which seems to occur whenever a local hypoxia or anoxia arises in the tissues without the immediate destruction of the whole tissue.

HISTOLOGY

Collagen and a Cellulose-like Substance in Fossil Dentine and Bone

The first direct evidence that certain organic components are retained in the fossil remains of vertebrates comes from the analysis by paper chromatography of specimens of *Dinichthys* of Middle Devonian age (380 million years old)[1]. This work has shown that degradation products of collagen can still be recognized. More recently[2], it has been demonstrated that fossil dentine and bone-like tissues in Devonian ostracoderms are capable of being decalcified and sectioned on a microtome. Further work at the Royal Dental Hospital, London, using normal histological staining techniques, has now indicated the presence of polysaccharides as well as collagen in the dentine and bone-like tissue of the ostracoderms. Using fossil bone belonging to a bison from the most recent Ice Age, and to *Dremotherium* from the Miocene (25 million years old), electron microscope photographs have been obtained at the Nuffield Orthopaedic Centre, Oxford, showing collagen fibrils and the intact walls of canaliculi[3]. Furthermore, X-ray diffraction of the same material has established that it is the tubular form of collagen that is present.

In the work now in progress, an attempt has been made to isolate the organic content in the bone of a prosauropod dinosaur from the Upper Trias (200 million years old), and in the dermal armour of further Devonian ostracoderms. One of the main difficulties encountered, however, has been that since only dilute acids or alkalis at room temperature can be used to isolate the collagen, although most of the mineral content can be removed, certain minerals have so far resisted solution. In the dinosaur, a manganese phosphate has been the major obstacle, while in the ostracoderms there is a residual aluminium silicate. These minerals have been identified by their X-ray diffraction patterns.

Nevertheless, electron microscope investigations of patches of almost completely demineralized bone in the dinosaur, and dentine and bone-like tissue in the ostracoderms, reveal a fibrillar structure; an electron-diffraction examination of the same material shows a mixture of mineral and collagen patterns. In addition, in the dentine of the dermal armour of the ostracoderms, electron microscopy shows that the dentine tubules are intact, while the electron-diffraction pattern indicates that their walls are composed of an organic compound. The material is similar in appearance and staining characteristics to other mammalian tissue components, which have been isolated for X-ray diffraction and have given a cellulose-like pattern.

PATHOLOGY

Paired Helical Filaments in Electron Microscopy of Alzheimer's Disease

In the light microscope, the characteristic change in the neurones of the cerebral cortex in Alzheimer's disease is the presence of dense bundles of argyrophilic fibrils. They are coiled into skeins or 'squash racket' shapes, and appear to fill most of the perikaryal cytoplasm, sometimes giving the cell a swollen appearance. It has been suggested by Divry[1] that the fibrils are extra-cellular except in the later stages of the change. The fibrils stain with congo red, and this results in a type of birefringence suggesting the presence of longitudinally arranged micelles in the fibrillar bundles. These well-known findings would lead one to expect the presence of fine filaments associated with these cells in the electron microscope, and if intra-cellular, these might be neurofilaments, which are suggested by Gray and Guillery[2] to be the basis of neurofibrillary argyrophilia.

This is a preliminary report of observations in the electron microscope on cortical biopsies from three cases of Alzheimer's disease, confirmed by light microscopy. In each case the biopsy was taken from the parietal lobe through a burr hole prior to ventriculography. The specimen was cooled rapidly below 20° C after removal and cut into small pieces in the fixative within 5 min of removal. The fixatives were 1 per cent OsO_4 or 0·6 per cent $KMnO_4$ buffered to pH 7·2, and fixation was continued for 4 h. The tissue was then dehydrated in alcohol and embedded in 'Araldite'. Most of the observations were made on material which had been stained in 1 per cent alcoholic phosphotungstic acid before embedding.

Most of the neurones seen were normal, being similar to those seen in biopsies from normal animals and from human cortex exposed for removal of tumours. A number of neurones, however, were very different from normal.

They contained thick bundles of parallel filaments of indefinite length, sweeping round the nucleus, often leaving only a thin rim of normal cytoplasm near the cell membrane. In places the filaments diverged or formed whorls, and some planes of section gave the impression of a ring. They could also be found in cell processes in the neuropil. In the later stages of the change the cytoplasm outside the bundles still appeared normal in fine structure, but compressed against the cell membrane, so that the ribosomes appeared as a dense mass. In the middle of the bundles, however, some lamellated bodies were found, similar to those described by Webster[3] as degenerating mitochondria. Other bodies were found in the bundles consisting of vesicles 500–1000 Å in diameter embedded in a dense granular mass of irregular shape, about 1μ in diameter.

At high magnifications the filaments composing the bundles were seen to be double helices. These consisted of two 100 Å filaments 150 Å from centre to centre, and completing one full turn in 1600 Å. Their appearance varied with the thickness and obliquity of the section. When parallel to the plane of section they appeared as helices, though this single appearance could be interpreted as a regular series of fusiform swellings, or at high packing densities, as tubules, as described by Terry[4]. In thick oblique sections they appeared as asymmetrical shapes, rough on one side and smooth on the other. Thin oblique or transverse sections did not show dots or circles, as would be shown by single filaments, tubes, or fusiform swellings, but dots paired with short curved segments, or two curved segments, or, very occasionally, a pair of dots. All these forms could be explained by a uniform helix with the dimensions described.

It is difficult to speculate on the nature of these structures. It is possible that they are neurofilaments occurring in vastly increased numbers and associated in pairs; though the individual filaments of each pair seem to be of higher density than neurofilaments, especially in unstained preparations. The tendency of these pathological filaments to stain with congo red suggests a similarity to amyloid, but the latter is known to be extra-cellular, and these filaments are intra-cellular.

Relationship of Gamma-Globulin to the Fibrils of Secondary Human Amyloid

AMYLOIDOSIS is the accumulation in characteristic locations of an eosinophilic substance or substances which are homogeneous when viewed with visible light and which often show characteristic staining reactions, consisting of metachromasia with crystal violet and positive staining with congo red. Recent electron microscopic investigations indicating that amyloid of diverse origins has a finely fibrillar ultrastructure[1] have been substantiated in a number of laboratories[2]. The exact nature of amyloid, however, remains obscure. Since amyloidosis often occurs in human beings in relationship to chronic inflammatory disease and in animals subjected to repeated antigenic stimulation, it has been suggested that there is a close relationship between immunological mechanisms and the pathogenesis of this disorder. The fluorescent antibody investigations of several workers[3,4] demonstrating the presence of γ-globulin in association with amyloid deposits has suggested to some that γ-globulin is an integral component of amyloid. Immunochemical work[5], however, as well as investigations of the disappearance time of human γ-globulin labelled with iodine-131 injected into patients with severe amyloidosis[6], have suggested that γ-globulin may not constitute a significant part of the structure of amyloid.

The isolation of the fibrillar component of amyloid in relatively pure form[7] and the recent development of a method of conjugating immune globulins to ferritin[8] provide a more precise method of detecting and localizing γ-globulin. The purpose of this communication is to report the use of the latter technique in investigating the interaction of anti-human γ-globulin with isolated amyloid fibrils.

Amyloid-laden liver, obtained at post-mortem examination from a patient with secondary amyloidosis, was homogenized, spun at 5,000 r.p.m. and the layer of amyloid fibrils removed and washed five times in saline, all operations being carried out in the cold. The conjugation of anti-human γ-globulin to ferritin was accomplished by the use of meta-xylylene diisocyanate according to the technique of Singer[8]. Conjugation was verified by the use of paper and immunoelectrophoresis; retention of antibody specificity and potency by Ouchterlony plates. Dialysed, lyophilized amyloid fibrils were suspended in saline, incubated with ferritin conjugated anti-human γ-globulin for 30 min at room temperature and then centrifuged for 10 min at 3,500 r.p.m. The supernate was discarded, and the precipitate was washed twice in cold physiological saline and twice in double-distilled water. In control experiments, the fibril suspension was incubated with unconjugated anti-human γ-globulin prior to incubation with the conjugate in an effort to block any reaction between the latter and fibrils. Also, incubation of fibrils with unconjugated ferritin was carried out. As a positive control, typhoid–paratyphoid vaccine was agglutinated with hyperimmune human serum; these coated organisms were afterwards treated in the same fashion as was the suspension of amyloid fibrils.

In all test systems aliquots of the final suspensions were suspended in 1–2 ml. of double-distilled water, a drop of suspension placed on an Athene grid for 2·5 min, and then treated with 1 per cent phosphotungstic acid by the hang-

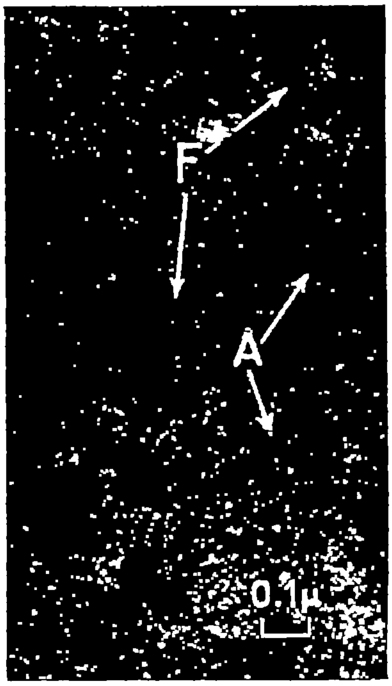

Fig. 1. Unshadowed preparation of human amyloid fibrils (*A*) exposed to ferritin conjugated anti-human γ-globulin (*F*). Note the random relationship of the ferritin conjugated antibody to the fibrils. (× 60,000)

ing drop method. After drying, grids were examined in an RCA-*EMU*-3*F* or a Siemens Elmiskop I electron microscope.

Fig. 1 illustrates the results of the exposure of isolated amyloid fibrils to ferritin conjugated anti-human γ-globulin. The labelled material (*F*) has only a random relationship to the amyloid fibrils (*A*), indicating that the former is not specifically bound to the latter. In the positive control specific adherence of the tagged antibody to the typhoid bacilli could be demonstrated. These results have been obtained consistently in other amyloid-laden tissues. These experiments support the hypothesis that undenatured human γ-globulin is not an intrinsic part of the amyloid fibril of secondary human amyloidosis.

Excretion of Orotic Acid and Orotidine in Heterozygotes of Congenital Orotic Aciduria

A NUMBER of purine and pyrimidine bases have been demonstrated in human urine in health or in disease[1-3]. Urinary excretion of orotic acid was found in studies of the propositus and so far only described case of congenital orotic aciduria[4]. Both orotic acid and orotidine (formed by the irreversible dephosphorylation of orotidine-5′-phosphate) are excreted in large amounts during therapy with 6-azauracil or 6-azauridine, compounds which on conversion to 6-azauridylic acid competitively inhibit the decarboxylation of orotidine-5′-phosphate to form uridine-5′-phosphate[5]. In work reported here evidence is presented for urinary excretion of orotic acid and orotidine by normal subjects, and for an abnormal pattern in presumed heterozygotes of congenital orotic aciduria.

Twenty-four urine collections (under toluene or in hydrochloric acid) were obtained from five previously described subjects with the erythrocyte enzyme pattern of heterozygous congenital orotic aciduria[6], from two subjects with clinical gout, and from seven normal controls. After preliminary observations failed to show any dietary influence the majority of determinations were made without dietary control except for the '*R*' family, who were examined while on a low purine–pyrimidine diet. Orotidine-^{14}C was prepared from orotidine-5′-phosphate labelled with carbon-14 (ref. 6) using *E. coli* alkaline phosphatase; orotic acid-^{14}C was obtained from commercial sources. For isotope dilution studies labelled orotic acid-^{14}C (2·5 μmole) and orotidine-^{14}C (2 μmole) were both added to a 10 per cent aliquot of a 24-h urine specimen and were initially purified by concentration on a charcoal column and chromatography on a 'Dowex 1-chloride' column as previously described[7]. The radioactive peaks, again concentrated on charcoal, were purified to constant specific activity by repeated ascending paper chromatographic separations, using several systems: *n*-propanol/formic acid/water (70 : 10 : 20) R_F's: orotic 0·39, orotidine 0·31; *n*-butanol/ethanol/formic acid/water (50 : 15 : 10 : 25) R_F's: orotic 0·41, orotidine 0·30; *n*-propanol/water (60 : 40) R_F's: orotic 0·53, orotidine 0·47. Concentrations of purified orotic acid and orotidine were determined spectrophotometrically in 0·1 N hydrochloric acid at 280 mμ and 266 mμ respectively, and radioactivity measured in a Packard Tri-Carb scintillation counter. The validity of the isotope dilution technique as used was supported by: similarity of chromatographic and ultra-violet spectroscopic characteristics of products purified to constant specific activity with those of authentic orotic acid and orotidine; recovery experiments with added authentic compounds; reproducibility of results using varying aliquots of urine; and conversion of recovered orotidine

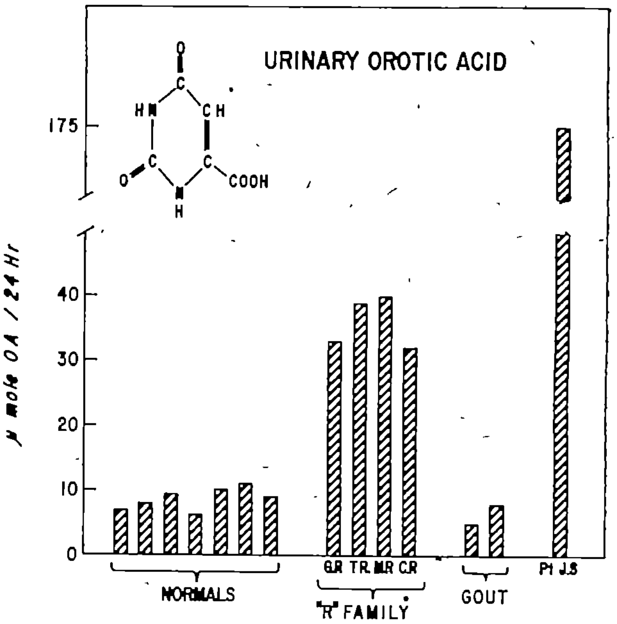

Fig. 1. Twenty-four-hour urinary excretion of orotic acid by control subjects, two patients with idiopathic gout, the parents and two siblings of the propositus of congenital orotic aciduria ('*R*' family), and by J. S., an additional subject with the erythrocyte enzyme defect of congenital orotic aciduria

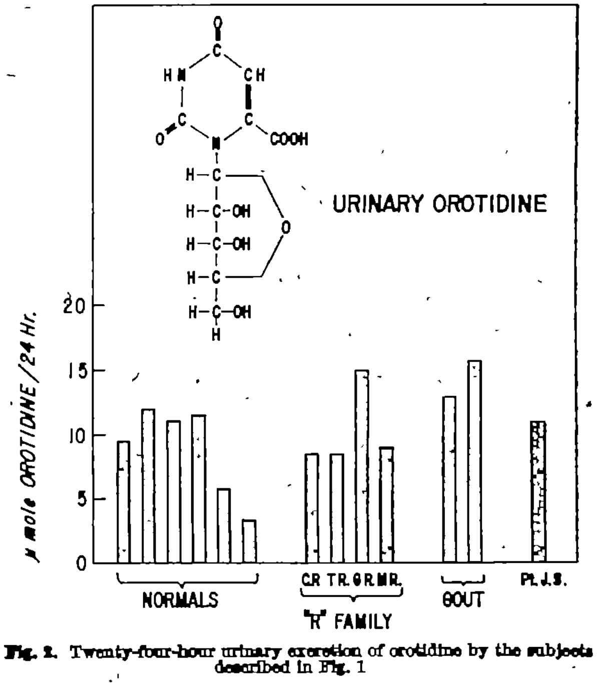

Fig. 2. Twenty-four-hour urinary excretion of orotidine by the subjects described in Fig. 1

to orotic acid of the same specific activity by acid hydrolysis (2·5 N sulphuric acid, 100° C, 1 h).

Normal urinary excretion of orotic acid was found to be approximately 9 μmole (1·4 mg) per 24 h (Fig. 1). Members of the '*R*' family, that is, the parents and two siblings of the propositus of congenital orotic aciduria, excreted orotic acid at approximately four times the normal rate. In subject J. S., unrelated to the '*R*' family but previously demonstrated to exhibit decreased erythrocyte activity of orotidylic pyrophosphorylase and orotidylic decarboxylase[6], urinary orotic acid was found to be 165–177 μmole/24 h on 8 repeated determinations on two urine collections. Excretion of orotidine averaged 9 μmole (2·5 mg) per 24 h in control subjects, with no abnormality observed in the five presumed heterozygotes of congenital orotic aciduria (Fig. 2). Alterations in the pattern of trace purines and increased excretion of 5-ribosyluracil (pseudouridine) have been described in primary gout[8]. No change in urinary orotic acid or orotidine was found in two gouty patients despite one collection being obtained during an untreated attack of acute gouty arthritis.

In summary, the normal urinary excretion of orotic acid and orotidine is in the range found for a number of other purine and pyrimidine compounds. Each represents approximately 0·1 per cent of the estimated daily rate of *de novo* pyrimidine synthesis[7]. The increased urinary orotic acid in presumed heterozygotes of congenital orotic aciduria is consistent with the previously described decreased activities of orotidylic pyrophosphorylase and orotidylic decarboxylase in erythrocytes from these subjects, and in contrast to the simultaneous increase in urinary orotic acid and orotidine produced by specific inhibition of orotidylic decarboxylase with 6-azauridine.

Plasma Triglycerides and Thrombosis in Rats

THROMBOSIS of the cardiac chambers occurs in rats given hypercholesterolæmic diets containing 40 per cent butter, 5 per cent cholesterol, 2 per cent cholic acid and 0·3 per cent thiouracil[1]. If butter is replaced by arachis oil, thrombosis does not occur, but fibrous atherosclerosis of the proximal aorta is seen instead[2]. Other fats besides butter, such as beef fat and hydrogenated arachis oil, are also thrombogenic, and the essential factor is a triglyceride containing a saturated fatty acid such as distearin-mono-olein[3]. The required triglyceride for atherosclerosis is less clear, but linoleic acid may be involved. Butter alone is not thrombogenic, and cholesterol, cholic acid and thiouracil are all essential for thrombosis, but thiouracil can be omitted if a highly saturated fat such as cocoa butter[4] is used.

Later work has concentrated on finding the essential biochemical differences between the atherogenic and thrombogenic systems. Major differences were found between experimental and normal rats but not between rats showing thrombosis or atherosclerosis. In both groups an increase in coagulability was demonstrated, caused by an elevation of coagulation factors and decreased fibrinolysis[4]. Biochemical examination of the plasma showed markedly increased cholesterol[5] and phospholipids[6] and total glycerides (triglycerides and phosphoglycerides)[4]. Of the total plasma fatty acids, arachidonic acid was diminished and oleic acid was increased[6]. In the present experiments attention has been given to the plasma triglycerides. High levels have been found only in those rats given a diet which cause thrombosis.

Groups of 8 rats were given various hypercholesterolæmic diets containing different fats previously investigated (Table 1)[2–4]. After one month of feeding, the rats were fasted for 24 h, killed with carbon dioxide and blood taken from the inferior vena cava using heparin as anticoagulant[4]. Plasma triglycerides were separated from the phospholipids using the method of Handel and Zilversmidt and estimations of triglycerides[7], cholesterol[4] and phospholipids carried out on the appropriate eluant from the silicic acid column. Free fatty acids were also estimated according to the method of Dole[8]. The results given in Table 1 also include pathological data from previous experiments in which the rats were given the diets until death or on conclusion of the experiment at 6 months[2–4]. There is a marked correlation between the ability of a diet to produce thrombosis and its effect on plasma triglycerides but no obvious correlation with cholesterol, phospholipid or free fatty acid levels. Thus the atherogenic arachis oil group has normal triglycerides. When thiouracil is omitted from the diet high levels are seen only with cocoa butter but not with butter.

Although comparison of the thrombotic system in the rat and the disease of coronary thrombosis in man has evoked some criticism[9], our group has always maintained that the system might provide valuable leads to future research in the field of thrombosis[10]. It is of interest, therefore, to note that the major lipid abnormality in patients with coronary heart disease is an increase in triglycerides[11], and it has been suggested that the incidence of the disease may be linked with plasma triglyceride levels[12]. The current results emphasize the importance of glycerides, and current investigations are concerned

Table 1. EFFECT OF HYPERCHOLESTEROLÆMIC DIETS ON VASCULAR PATHOLOGY AND PLASMA LIPIDS

A Factor in the Serum of Tumour-bearing Rats which is Deleterious to Cells in Tissue Culture

In attempts to improve the growth of a transplantable rat carcinoma (*S.O.K.*1)* in tissue culture by the addition of rat serum, it was observed that sera from rats bearing *S.O.K.*1 did in fact exert a deleterious effect on the cells. This observation was investigated.

*S.O.K.*1 is a squamous cell kidney carcinoma which arose spontaneously in 'John's' isogenic strain of rats. The tumour is regularly transplanted subcutaneously in these rats and up to the time of writing has been through 23 transfers. Primary cultures of the tumour were grown in a lactalbumin hydrolysate medium with 20 per cent calf serum and all tests were put up in a modified Parker's 199 medium[1]. Cultures were grown for 24 h or 48 h before addition of the rat serum and results were recorded after a further 24 h incubation.

The effect of serum from *S.O.K.*1 bearing rats on cells in culture was to cause them to lose their ability to adhere to the glass. Ultimately the cells died, but it was impossible to tell whether death was due directly to some deleterious factor in the serum or to the inability of the cells to survive in an unattached state. Some cell lysis occurred, but again this could not be definitely attributed to this factor.

In order to test the point, 32 sera from tumour-bearing rats have been examined as 10 per cent solutions in 199 medium and compared with a normal serum control. Results are shown in Fig. 1. It can be seen that the effectiveness of the sera against *S.O.K.*1 cells in culture increased with the tumour size. Fig. 2 illustrates the results of a single experiment.

Experiments showed that the tumour factor was also active against other cell lines, namely, rat embryo, *R.I.B.5** (a transplantable rat sarcoma) and *Hep.* 2.

Sera of rats examined after operative removal of *S.O.K.*1 showed the usual activity in tissue culture immediately after operation but it was completely lost after 7 days. The activity was, however, restored by a regrowth.

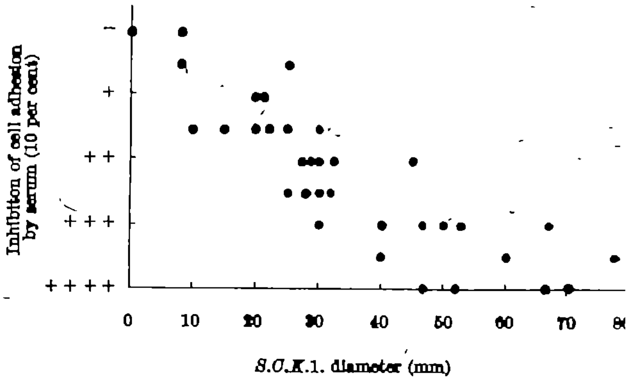

Fig. 1. Correlation between size of tumour and inhibition of adhesion of cells in culture by serum. + + + +, Complete inhibition; + + +, + +, +, approximately 75, 50 and 25 per cent inhibition, respectively

Interstitial fluid from *S.O.K.*1 caused complete or almost complete inhibition of cell adhesion when added to cultured cells. Normal tissue fluids tested did not have this effect. This gives further confirmation of results reported here. The factor was also found on dialysis to appear in the dialysate so presumably is small enough to pass fairly freely into the rats' circulation.

A similar dialysable factor which is cytotoxic for strain *L* cells in culture has been demonstrated by

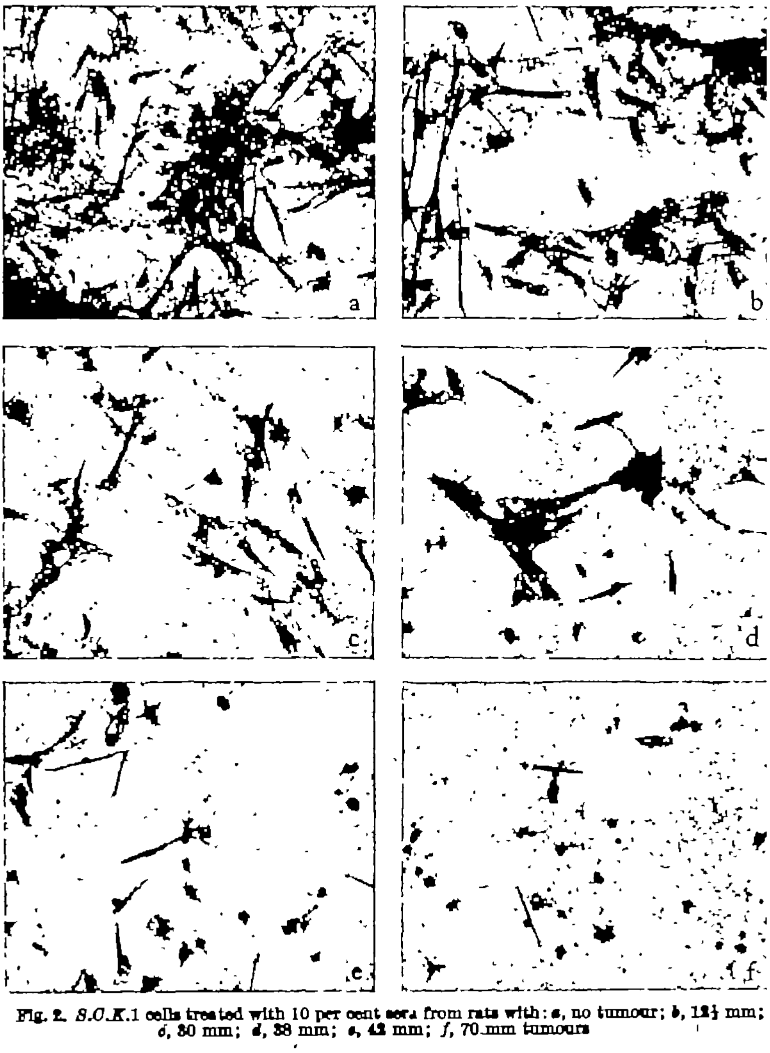

Fig. 2. *S.O.K.*1 cells treated with 10 per cent sera from rats with: *a*, no tumour; *b*, 12½ mm; *c*, 30 mm; *d*, 38 mm; *e*, 42 mm; *f*, 70 mm tumours

Renal Disease associated with Positive Lupus Erythematosus Tests in a Cross-bred Strain of Mice

A STRAIN of mice *NZB/BL* suffering from an auto-immune type of hæmolytic anæmia has been described[1,2]. Since then it has been shown that approximately 4 per cent of this strain have positive lupus erythematosus cell tests and that many of the animals show renal changes resembling those seen in human systemic lupus erythematosus[2,3]. In this paper it was also shown that F_1 and F_2 progeny derived from a cross between mice of the *NZB/BL* and the *NZY/BL* strains showed a low incidence of hæmolytic anæmia but 25 per cent of the animals had positive lupus erythematosus cell tests and all had renal changes resembling lupus nephritis. These animals died from renal failure within 18–24 months of age.

Recently, hybrids derived from a cross between the *NZB/BL* strain and an inbred strain of white mice known as *NZW* have been shown to die of renal failure within 8–10 months. All animals show positive lupus erythematosus cell tests and all have florid renal changes showing close identity with those seen in human lupus nephritis.

The kidneys may appear enlarged, dusky pink in colour, flecked with multiple red specks, or contracted, typically *café au lait* coloured and granular. Early glomerular changes are hypercellularity with unfolding and thickening of the capillary walls to form typical wire-loop deformities. Lymphoid deposits around the hilar vessels spread along their course towards the cortex and are usually heavily populated with plasma cells and Russell body forms. The renal tubules contain hyaline casts of periodic acid–Schiff-positive material and often granules or droplets of similar material may be seen in the cytoplasm of the proximal convoluted tubules.

Other lesions are found according to the stage or intensity of the disease process. In the most florid cases large areas of fibrinoid necrosis involve the basement membrane and cellular elements of the glomerulus, while others show numerous so-called hyaline thrombi and occasional hæmatoxylin bodies. Approximately one-third of cases show fibrinoid necrotic lesions in the walls of medium and small renal vessels. In these cases similar vascular changes have been noted in the spleen, lymph nodes, stomach, thyroid and myocardium.

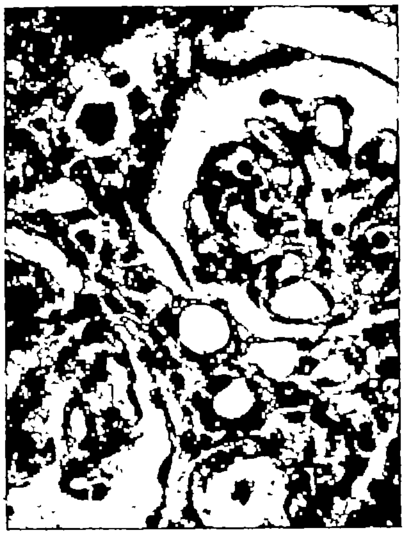

Fig. 1. Wire-loop deformity of glomeruli (hæmatoxylin–eosin, × c. 320)

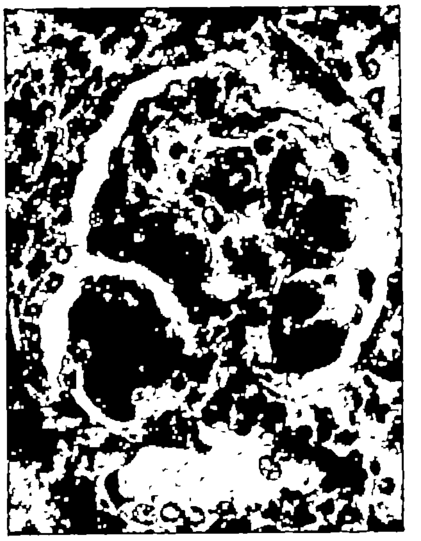

Fig. 2. Hypercellularity and fibrinoid necrosis of glomerular tuft (hæmatoxylin–eosin, × c. 320)

It is believed that this hybrid strain will prove invaluable in research into the nature and therapy of systemic lupus erythematosus.

RADIOBIOLOGY

Cæsium-137 in Dried Milk Products in Relation to Phytoclimatic Zones

A RECENT evaluation of radiological data gathered by the U.S. Atomic Energy Commission's Health and Safety Laboratory includes a statement that the concentration of fission products in commercial milk is essentially independent of total rainfall[1,2]. However, the precipitation values were presented as arbitrary ranges and the landscape units used were not strictly biological regions. The purpose of this communication is to show that if radiological data from the same source are arranged according to natural landscape units a relationship between phytoclimatic zones and the cæsium-137 content of milk is indicated.

For our purpose, the geographical region considered is the north-western portion of the United States where broad areas are mapped as distinctive natural vegetation zones[3]. Such broad areas are necessary to allow reasonable assurances that milk sample stations actually derive milk from an area representative of a particular vegetation zone.

Ten of eleven milk sampling stations in the north-west region were grouped into one of three natural vegetation zones (Table 1). Portland, Oregon and Burlington, Washington, were assigned to the Pacific north-west coniferous forest zone. Bismarck, Bottineau, and Cando, North Dakota; and Mitchell, South Dakota, were assigned to the grassland zone. Sunnyside, Washington; Payette and Idaho Falls, Idaho; and Monroe, Utah, were assigned to the sage-brush zone. Because of its proximity to the Wasatch Mountains, which provided a diversity of vegetation zones within a small area, the milk sampling station of Ogden, Utah, was excluded.

Cæsium-137 is deposited on aerially exposed plant parts directly from the atmosphere and the amounts ingested and assimilated by grazing animals are dominantly from this source rather than from plant uptake via contaminated soils[4]. Total precipitation is regarded as important in depositing cæsium-137 over landscapes and the amounts deposited are related to the amount of precipitation; moist regions receive more cæsium-137 than regions of less moisture[5].

The cæsium-137 content of milk samples in pc./g potassium from stations grouped according to vegetation zones is presented in Table 1. Milk products from sampling stations in the coniferous zone averaged 90 pc./g potassium as compared with only 54 and 37 for grassland and sage-brush zones. Total precipitation from weather stations near the milk sampling stations showed the coniferous forest zone stations as receiving an average of 61 in. from January 1, 1959, until June 1960. This was compared with an average of only 29 and 12 in. from grassland and sage-brush zones respectively. It is realized that precipitation readings from a few stations probably do not represent an accurate measurement of the precipitation over the entire milk harvest areas; nevertheless, natural vegetation reflects the biological effectiveness of precipitation and the boundaries of these may be used to delimit long-term biological climates. It has long been recognized by plant ecologists that total annual precipitation in the north-western United States is not sufficient to differentiate sage-brush and grassland zone climates[6]. The seasonal distribution of precipitation in the sage-brush zone is concentrated in winter months, while that of the grassland zone is concentrated in spring and summer (Table 1). Seasonal precipitation could greatly influence the amounts of cæsium-137 deposited on foliar surfaces. In temperate climates having a definite seasonal agricultural yield foliar deposited cæsium-137 reflects the amounts largely accumulated during the summer photosynthetic period. Forages grown in the semi-arid sage-brush zone seldom experience summer precipitation and growth water is supplied by irrigation. In the grassland zone growth of forage crops and summer precipitation coincide to yield higher cæsium-137 values in contrast to the non-synchrony of biological and meteorological events and lower cæsium-137 values in the sage-brush zone.

Table 1. AVERAGE CÆSIUM-137 PC./G POTASSIUM IN DRIED MILK PRODUCTS AND PRECIPITATION FOR MILK SAMPLING STATIONS IN THE NORTH-WESTERN UNITED STATES, JANUARY 1959–JUNE 1960, GROUPED ACCORDING TO NATURAL VEGETATION ZONES

Vegetation zone	Sample station	No. of samples	avg. ^{137}Cs pc./g K	Precipitation total inches	% of ppt in winter months
Coniferous forest	Portland, Oreg.	65	89	67	52
	Burlington, Wash.	75	92	55	47
			avg. 90	avg. 61	
Grassland	Bismarck, N.D.	67	65	20	10
	Bottineau, N.D.	77	51	29	5
	Mitchell, N.D.	58	42	37	12
	Cando, N.D.	31	48	—	—
			avg. 54	avg. 29	
Sage-brush	Sunnyside, Wash.	78	22	9	55
	Payette, Ida.	70	43	18	49
	Idaho Falls, Ida.	73	49	9	28
	Monroe, Utah	73	34	—	—
			avg. 37	avg. 12	

The higher average cæsium-137 content of dried milk products produced in the moist forest zone appears related to the greater precipitation in this zone in contrast to the grassland and sage-brush zones. The lower average cæsium values in milk products produced in the sage-brush zone in contrast to grassland zone appear as a result of a non-synchrony of phenological and meteorological events induced by land management practices.

To test statistically the effect of vegetation zones in relation to the cæsium-137 content of milk an analysis of variance was performed which included seasonal effects The hypothesis of no zonal effect was rejected at the 1 per cent level of significance. Additional inferences were obtained by subsequent tests for judging contrasts[7]. All three contrasts between means were significant at the 1 per cent level. The computed values: $\psi_1 > 12$ pc. cæsium-137/g potassium; $\psi_2 > 32$ cæsium-137 pc./g potassium; where ψ_1 is the difference between the means of the grassland zone and the sage-brush zone and ψ_2 is the difference between the means of the forest and grassland zones.

Decreased Incorporation of Phosphorus-32 in Radiosensitive Organs after Whole-body Irradiation in Rats

CONSIDERING the significant role of phosphorus in transferring and in passing energy into the organism, we investigated the distribution of the intravenously applied $Na_2H^{32}PO_4$ in the individual organs of the non-irradiated group of five rats and the group of five rats exposed to an X-ray dose of 600 r. Irradiation was carried out with the Mackrophos 250 X-ray apparatus of 200 kV, 15 m.amp, filtration 0·5 mm copper + 0·5 mm aluminium, focus distance of 120 cm. dose rate of 10 r./min. The irradiation doses were controlled by a Mekapion dosimeter.

$Na_2H^{32}PO_4$ was applied to the experimental animals, 25 μc./200 g weight with an original specific activity of 13·1 mg phosphorus/ml., *p*H 7·2.

The rats were divided into groups (each group consisting of five rats) and the application was made for one day for all animals. The rats were killed by decapitation after 24 h, 3, 7, 14 days and the activity in blood, bone, marrow, brain, thymus, spleen, liver, kidney, small intestine, muscles, testes and bone compacta was examined. The activity was determined individually after scoring organs by means of the end-window Geiger–Müller tube (type 33/50), window thickness 4·0–5·2 mg/cm^2.

The mean error was calculated from the formula $\delta = \pm \sqrt{\frac{\Sigma \Delta^2}{n(n-1)}}$; the mean error is shown in Fig. 1, without making use of the samples of bone marrow, since we were short of sufficient material for the investigation and therefore we summarized samples of five animals.

The results obtained may therefore be divided into three groups. The first group consists of the radiosensitive organs: bone marrow, thymus, spleen and intestine As is apparent from Fig. 1, the percentage of the incorporated phosphorus-32 in these organs of irradiated animals is significantly smaller during the whole period of investigation than in the case of non-irradiated animals

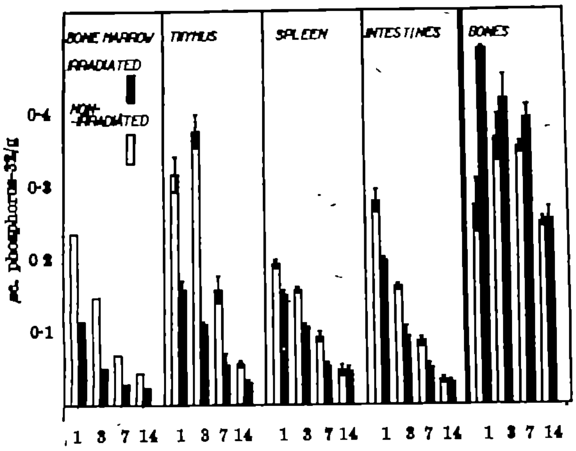

Fig. 1. Incorporated phosphorus-32 in radiosensitive organs and bones in controls and whole-body irradiated rats

Together with the progressive regeneration of the post-irradiation changes we found, on the fourteenth day of the investigation, that the values of the incorporated phosphorus-32 were normal.

A rather different character of incorporation is observed in the compact bone where the degree of uptake of phosphorus-32 is greater during the whole period of investigation in the irradiated animals.

The level of phosphorus-32 in the blood is significantly higher the first day after the irradiation, and from the seventh day it increases substantially.

Our results are in agreement with the findings of Olson *et al.*[1] and Florsheim and Morton[2]; but they differ from the findings of Sherman and Forssberg[3], who observed an increase of phosphorus compounds (sodium phosphate—for labile phosphates in the acid medium, ATP and for soluble phosphates in the acid medium) in liver.

The increased values of phosphorus-32 in the blood of irradiated animals are in agreement with the results obtained (to be published) concerning the excretion of phosphorus-32 by the urine in the irradiated rats[4].

With regard to the phosphorylation processes, the decrease of the phosphorus content in the deoxyribonucleic acid after irradiation[5,6], we conclude that our results are in agreement with the aforementioned findings.

It has been shown that the radiosensitive organs are unable to make use of the applied phosphorus metabolically after irradiation.

Factors modifying the Post-Radiation Effects of Homologous Spleen

IN 1954 Barnes and Loutit[1], investigating an unrelated problem, observed that splenic cell suspensions from infant mice can protect adult homologous recipients from the early death induced by supra-lethal X-radiation. The protected animals died after 30 days apparently from what is now recognized as 'secondary disease'. Using different mouse strain combinations, Schwartz *et al.*[2] noted that administration of adult parental splenic cells into supra-lethally X-radiated F_1 hybrid animals results in an early death of the injected recipients, to the extent that they die even earlier than the uninoculated irradiated controls. A similar phenomenon of early mortality was also observed by Cole *et al.*[3], who showed that parental adult mouse spleen cells induce death within a week when given to sub-lethally X-radiated F_1 hybrids. Splenic cells from the same parental strain were also able to induce death within 8 weeks in some of the injected F_1 non-irradiated recipients. Makinodan *et al.*[4], using completely homologous combinations and supra-lethal X-radiation, were also able to confirm the observations of the early death induced by the infusion of the splenic adult cells.

As an explanation for the 'killing effect' induced by injection of homologous adult spleen cells the hypothesis was advanced that immunologically competent donor cells are rapidly established within the defenceless host and kill it by an overwhelming graft-versus-host reaction. With infusion of infant homologous spleen cells the early 'killing effect' is avoided presumably because the donor cells are immature and incapable of immunological reaction. The recipients are protected and survive the early lethal effects of acute X-radiation; they succumb, however, later as a result of a secondary disease appearing as soon as maturation restores the immunological competence of the donor cells. In this case the sequence of events bears a striking similarity to the phenomena observed when adult homologous bone marrow is infused in similar circumstances. Adult marrow differs from adult spleen in that the former contains only few immunologically reactive elements. Similarly, and in contrast to the adult spleen, the infant spleen consists largely of hæmopoietic elements while the immunologically active cells are limited in number. It is, therefore, conceivable that the chronological difference in the appearance of the graft-versus-host reaction produced by the respective infusion of adult and infant splenic cells in a homologous recipient is merely an expression of the difference in the number of immunologically competent cells present in the two organs. The differences, in other words, between adult and infant spleens in their behaviour as homologous donors could be explained on a simple quantitative basis.

In order to investigate this hypothesis it is necessary to examine parameters influencing the phenomenon of the 'splenic death': (*a*) dose of irradiation; (*b*) degree of histo-incompatibility; (*c*) time of the post-radiation splenic injection; (*d*) dose of splenic cells injected; (*e*) age of the donor of splenic cells. This communication deals with the examination of the first three parameters.

BDF_1 female mice 18–25 weeks old were used as recipients. Splenic cell suspensions were prepared from female *CBA*, *A* and C_3H mice. The animals were irradiated with a clinical X-ray unit operating at 200 kVp, 20 m.amp. with 0·50 mm aluminium and 0·25 mm copper added filtration. Target distance was 7 cm and dose rate 118–120 r./min. Total doses used are referred to in the text. All splenic infusions were given at a standard dose of $12·5 \times 10^6$ cells via tail vein, within the first 24 h after exposure. Non-infused animals served as controls. No supportive therapy was given. The animals were observed for a period of 60 days.

Table 1 summarizes the effects of various X-ray exposure-levels on the 'killing effect' of the spleen. With doses varying from 400 to 500 r. no deaths were observed either in the control or among the treated animals. Exposures at 600 r. caused death within three weeks to all the animals treated with *CBA* or *A* spleen cells. During the same period the animals infused with C_3H spleen cells as well as the control animals survived. With C_3H spleen cells the 'killing phenomenon' was demonstrated at the 675-r. X-radiation level. All recipients

were dead within three weeks in contrast to the radiation control animals, which showed an insignificant rate of mortality during the same period of time. Above this radiation-level, no homologous spleen recipient survived more than 21 days. In fact the majority of the animals died within the first 15 days. The results suggest the existence of a radiation threshold, above which all injected animals die. Within the given strain combinations, the phenomenon is reproducible when the splenic cell dose and the post-irradiation time of injections are kept constant.

In mice, apart from other apparently non-critical systemic damages, sub-lethal radiation seems to inflict its major effect on the reticuloendothelial system of the animals. The difference between survival and death after varying amounts of X-radiation may depend on the degree of damage to the immunologially competent *RE* cells in the host. When immunological responsiveness was not sufficiently impaired by X-radiation the host could reject the donor spleen cells and survive. Larger amounts of irradiation presumably destroyed this capacity to react against the donor spleen cells, which were therefore able to act against the host. This postulate is attractive, and it could be greatly enhanced if the X-radiation threshold proved to be dependent on the number of splenic cells infused. Should this not be the case, however, other explanations must be sought, for example, a possible 'all-or-none' damaging effect of sub-lethal X-radiation on the *RE*-host system, which either survives or is destroyed as a whole.

The results also indicate that histo-incompatibility plays an essential part in the induction of the 'killing effect'. They also indicate that the *H*–2 locus is not the only locus which determines the degree of histo-incompatibility. Spleens from *CBA* and *A* animals although of varied *H*–2 locus composition show identical X-radiation threshold as to the 'killing effect'; on the other hand, *CBA* and *C_3H* donor spleen have different thresholds in spite of their $H\text{-}2^k$ similarity.

Another aspect of interest is that the 'killing effect' depends on the time of the post-radiation administration of the homologous spleen suspensions (Table 2). The 'killing effect' is always present when infusions are made within 20 h following X-radiation. The phenomenon disappears when the spleen cells are given 5 days after exposure to the threshold dose of X-rays. It is interestir to note that the lethal effect of homologous spleen is sti present 5 days later if the recipient is exposed to high X-ray doses (Table 2). An explanation for this 'tim effect could be that the recovery of the host *RE* syste allows the rejection of the splenic graft. Supporting th explanation is also the fact that mice infused at day 5 n only survive but do not develop secondary disease at later stage.

Table 2. EFFECTS OF THE POST-X-RADIATION INFUSION TIME AND THE X-RADIATION DOSE ON THE LETHAL EFFECT OF HOMOLOGOUS SPLEEN

X-ray dose (r.)	Donor strain of 12·5 × 10⁶ spleen cells	No. of BDF_1 recipients	Post-rad. infusion time	Survival for 21 days
600	*A*	22	24 h	none
600	*A*	22	5 days	all
675	*A*	11	24 h	none
675	*A*	11	5 days	none

Addendum: During the preparation of this manuscript dublication (*Transp. Bull.*, 30, 29; 1962) by G. E. Cosgrov *et al.* appeared describing similar results, in parental *F* hybrid mice combinations.

Unfavourable Response of Radiation Nephritis to Administration of L-Triiodothyronine

RADIATION injury is a dynamic state, not a static one and therefore feasibly modifiable[1]. Numerous compound have been tested for possible advantageous effects o radiation injury, but with the exception of 3,5,3′-L-tri iodothyronine (T-3), administration of these agents witl established damage has not been beneficial. It is o interest that in spite of the apparent property of T-3 t sensitize tissues to irradiation[2,3], this same material i able to alter favourably tissue injured by irradiation.

L-Triiodothyronine was initially selected for investiga tion by Glicksman *et al.* as a possible modifier of radiatio injury on the basis of observations that thyroid analogue caused decrease in established radiation damage of ski and subcutaneous tissues in patients previously irradiate for carcinoma of the thyroid. Their recent reports[4,] demonstrate a favourable response of radiation ski necrosis, ulceration, and fibrosis in humans and experi mental animals to T-3 administration.

T-3 causes marked decrease in subcutaneous fibrosi and improvement in the blood supply. Since the respons of kidneys to high doses of radiation is, as in the skin primarily a fibrotic and atrophic process, it seeme reasonable that T-3 might also have a salubrious effec on heavily irradiated kidneys.

To test this hypothesis the left kidneys of 14 youn adult New Zealand rabbits, weighing an average o 1·9 kg, were irradiated *in vivo* to a total dose of 3,90 rads (three treatments of 1,300 rads a week apart) wit cobalt-60. Eight weeks after conclusion of irradiatio the animals were randomly divided into two groups Thereafter, the first group of rabbits received 25 μg/k T-3 subcutaneously daily. The other group was com posed of control animals and received no further treat ment.

Table 1. STRIPPED KIDNEY WEIGHTS (G) AT NECROPSY

Weeks post-irradiation	Control group Left kidney	Right kidney	T-3-treated group Left kidney	Right kidne
20	4·0	16 8	1·6	12·2
20	4·5	7 7	2·3	11·2
20	4·0	6·4	2·8	11·0
26	1·8	12·0	1·9	13·0
26	4 2	18 0	0 5	12·5
26	2·6	9·4	1·0	10 6
26	2 4	13 2	2·3	10·0
Average	3 4	11·9	1 8	11·7

At necropsy, 20 and 26 weeks post-irradiation, the stripped kidney weights were recorded. As shown in Table 1, the average weight of the control left kidneys was 3·4 g and that of the kidneys from the T-3 treated animals was 1·8 g. The difference in weights is statistically significant ($P < 0·01$) in spite of the small number of animals. The average weights of the right kidneys were 11·9 g and 11·7 g respectively. At necropsy the control animals were slightly heavier (2·9 kg average) than the animals treated with T-3 (2·5 kg average); but the absence of difference in the right kidney weights excludes the importance of this discrepancy.

Evaluation of histological change in the kidneys of the two groups is in progress. Preliminary interpretation suggests correlation with the gross findings; that is, more severe histopathologic change in the irradiated kidneys of the T-3 treated animals than in the irradiated kidneys of the control group.

One can argue that the dose of T-3 used was too large to alter the severe radiation nephritis produced. However, Glicksman and associates[4,5] kept their patients and experimental animals at near toxic levels to achieve modification of the skin damage. In spite of T-3 administration the rabbits in our experiment maintained their average weight of 2·5 kg, so the dosage was not apparently excessive.

Possibly at lower radiation doses there would be less severe reaction which could be altered by T-3. However, the apparent detrimental effect at the radiation dose used in this series belies this supposition.

We have no reasonable explanation for this unexpected deleterious effect of 3,5,3′-L-triiodothyronine. Nevertheless, the presented results suggest that T-3 is not an effective modifier of radiation damage, at least that involving the kidneys of rabbits.

BIOLOGY

Occurrence of a Warty Layer in Vascular Cells of Plants

Electron microscopic observations have revealed that mature tracheids of conifers are lined on the inside with a warty layer. It consists of more or less spherical particles of an average diameter of 0·1–0·3μ, which are often covered by an amorphous layer. The appearance and properties of the warty layer vary according to species[1–5]. It develops during the last stages of cell differentiation and consists of the remnants of the protoplast. Consequently the existence of a warty layer should not be limited only to the conifer tracheids. Light microscopical observations have shown that vessels, tracheids and fibres of many hardwood species have also a granular appearance[6]. Our investigations with the electron microscope demonstrate that this structure corresponds to the warty layer (Fig. 1).

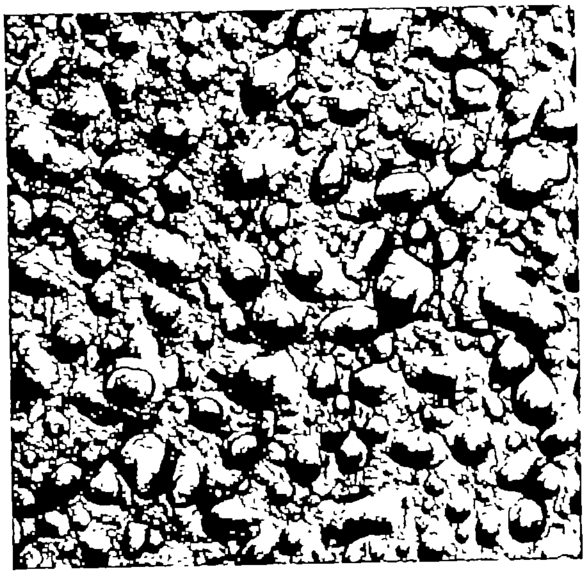

Fig. 1. Warty layer covering the inner side of a vessel wall of *Fagus silvatica* (× 10,000)

The presence of a warty layer has been reported so far only for lignified cell elements of woody species. If the origin of this layer is connected with the death of protoplasm in the final stage of differentiation of vascular cells, it might exist in such cells of herbaceous plants as well. Observations with the light microscope of longitudinal sections of several genera such as *Fuchsia*, *Geranium*, *Helleborus*, *Lavendula*, *Malva*, *Mesembrianthemum*, *Plantago*, *Rosmarinus*, *Saxifraga*, *Vicia*, have established that vascular cells in stems and leaves are covered with a granular layer. In the different plants it can be seen with varying degrees of clarity. For a more detailed investigation *Plantago major* L. was selected. Vascular bundles from petioles and leaves were fixed in osmium tetroxide, embedded in epoxy resin, and the sections were stained with lead acetate.

Vessels and also fibres show in the late stages of differentiation a distinct lining of the wall, which consists of two

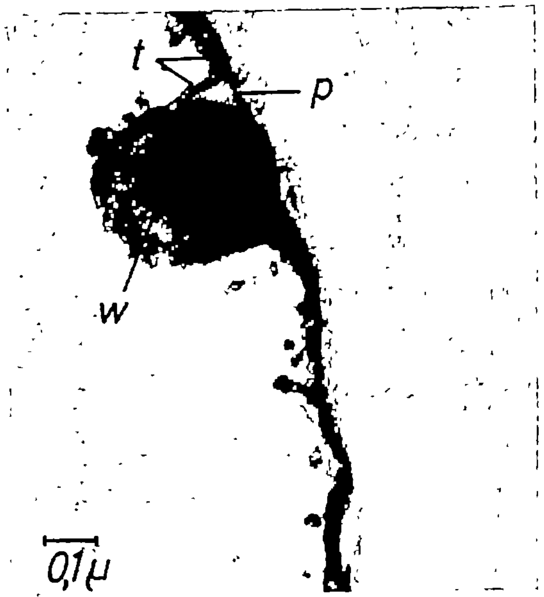

Fig. 2. Portion of vessel wall in section from *Plantago major* showing wart (*w*) which rests on the plasma membrane (*p*) and is covered by the tonoplast (*t*) (× 66,000)

membranes—the plasma membrane and the tonoplast—with the remaining cytoplasm between them. Particles of varying size are present within the dying cytoplasm. With progressive differentiation the cytoplasm condenses and the tonoplast is brought close to the plasma membrane. The particles which remain are sandwiched between these membranes and form excrescences into the cell lumen (Fig. 2). In surface view these particles give the appearance of a warty layer. Thus the origin of the warty layer in *Plantago* is similar to that recently found by Wardrop and Davies[7] for the tracheids of *Actinostrobus*. However, in the case of *Plantago* we do not regard the warts as local thickenings of the cell wall, even in part, but rather as components of the cytoplasm which have become cemented to the wall in the last stages of differentiation.

The observations recorded here have shown that the warty layer is not only present in the lignified cells of woody species, but also in the vascular cells of herbaceous plants. Therefore its occurrence can be regarded as a general structural feature of plant cells, which is derived from the dying protoplast.

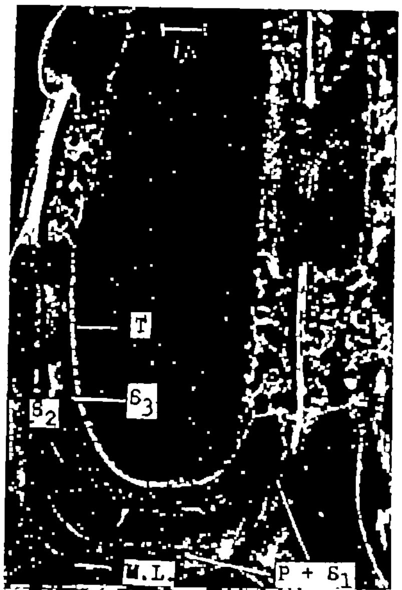
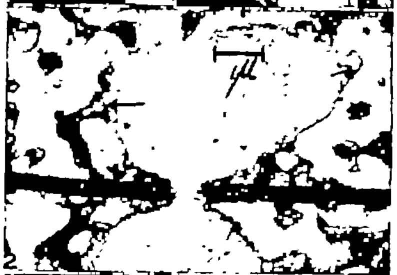
Nature of Vestured Pits in Angiosperms

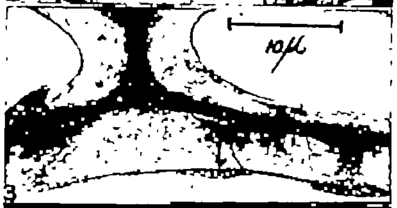
VESTURED (cribriform) pits occur in many families of the dicotyledons and in many instances serve as taxonomic criteria between families. The nature of the vestures was first recognized by I. W. Bailey[1] as "minute outgrowths from the free surfaces of the secondary wall". General confirmation of this view has been obtained in a recent electronmicroscopic study of the vestured pits of *Eugenia* sp. In Fig. 1 the general form of the vestures and their attachment to the cell wall are apparent. In the unshadowed section in Fig. 2 it can be seen that the vestures represent outgrowths of the secondary cell wall and in some instances appear to arise from the pit membrane as well. It may be noted from Figs. 1 and 2 that the texture of the vestures is heterogeneous in that the outgrowth of the cell wall appears to be covered by a membrane which is extremely dense to electrons. This membrane is continuous over the vestures and forms a lining around the inner surface of the cell wall adjacent to the lumen (Fig. 1).

Sections cut after maceration with hdryogen peroxide acetic acid showed that this treatment removed the lining membrane, but the enclosed outgrowth of the cell wall forming the vesture was attacked at apparently the same rate as the cell wall itself. The lining membrane (Figs. 1 and 2) was strongly absorbing in ultra-violet light. In some instances the vestures extended laterally beyond the aperture into the cell lumen (Fig. 3).

In view of recent investigations in this laboratory into the nature of the wart structure of gymnosperm tracheids which showed it to consist of a number of outgrowths of the inner layer of the secondary wall, it is reasonable to suppose that the vestures represent an analogous type of cell wall sculpturing in angiosperms. In cells where the vesturing extended beyond the pit aperture structures closely resembling the wart structure of gymnosperms were observed (Fig. 4). The wart structure in angiosperms has already been recognized by Liese and by Harada (private communications*). It is assumed, by analogy with studies of the development of the wart structure[2], that the dense membrane lining the cell lumen (Figs. 1 and 2) corresponds to the "terminal lamella" of Frey-Wyssling[3], and, as pointed out elsewhere[4], arises from the denatured membranous elements of the cytoplasm.







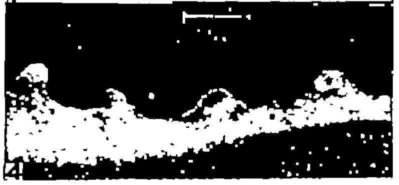


Fig. 1. *Eugenia* sp. A transverse section showing vestured pits between two vessels (right) and a vessel and parenchyma cell (left). Shadow-cast with platinum–palladium. $P + S_1$, Primary wall and outer layer of the secondary wall; S_2, middle layer of the secondary wall; S_3, inner layer of the secondary wall; T, terminal lamella

Fig. 2. An unshadowed section similar to Fig. 1 showing the continuity of the vestures with the cell wall (arrows). Note the difference in scattering power of the primary wall in the pit membrane as compared with the cell wall

Fig. 3. *Eucalyptus regnans*. An ultra-violet photomicrograph of a transverse section through part of a vessel and adjacent tracheids showing the ultra-violet absorption of the vestures and their lateral extension beyond the pit apertures of the vessel

Fig. 4. *Eugenia* sp. Part of a transverse section of the cell wall of a vessel similar to that in Fig. 1, showing the wart structure. Shadow-cast with platinum–palladium

An investigation of the development of vestured pits a special aspect of the general problem of cell wall rmation is in progress.

Incidental to the foregoing observations, it may be noted Fig. 1 that at the pit border the inner (S_2) and outer ,) layers of the secondary wall are not confluent.

Soluble Components of the Cambial Zone of *Eucalyptus regnans* F. Muell.

SEVERAL investigators have shown that the nutrient ids in the phloem and, in some instances, the liquors in e cambium of arborescent gymnosperms and angio-erms contain some of the following constituents[1]: mono-ccharides, chiefly glucose and fructose with traces of ntoses (mainly xylose); uronic acids, sorbitol and nnitol; disaccharides, chiefly sucrose; trisaccharides, including raffinose and 1^F-β-fructosylsucrose; higher oligosaccharides such as stachyose and verbascose; phenolic glycosides; oxalic, succinic, citric and lactic acids; amino-acids and peptides; inorganic salts: etc.

The work reported here represents an attempt to identify and to estimate quantitatively the major soluble carbohydrate substances of the cambial zone of *Eucalyptus regnans*. Shortly after the vernal resurgence of cambial activity, the bark was stripped from freshly felled trunks of several 18-year-old trees of *E. regnans*. Immediately after removal of the bark, the soft outer layer of the logs was collected by means of a 'Perspex' scraper[2]. The scrapings, which included the cambium and adjacent differentiating xylary elements (that is, the cambial zone), were plunged into boiling ethanol (final concentration 80 per cent) in order to inhibit enzyme activity. The subsequent examination of the cambial material and the results obtained are outlined in Fig. 1. The sub-division of soluble materials into acidic, neutral and basic fractions was achieved by the use of ion exchange resins 'Amberlite *IR* 120' (H) and 'Duolite *A* 4' (OH).

The substances present in acidic fraction I were identified by paper chromatography. The presence of a spot corresponding to glucuronolactone and the absence of a brick-red colour when the uronic acid spot was sprayed with the basic lead acetate reagent of Gee and McCready[3] indicated that the uronic acid detected was glucuronic acid rather than galacturonic acid. The occurrence of

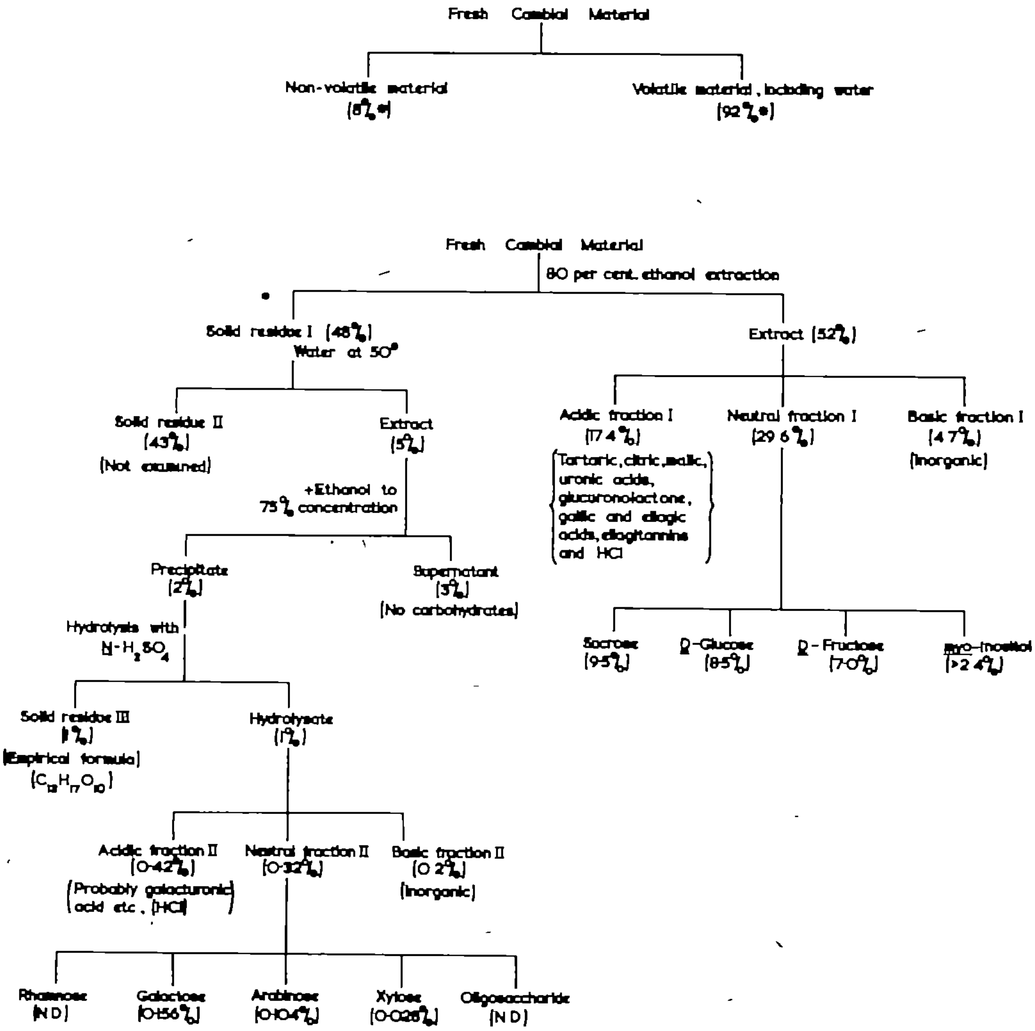

Fig. 1. Fractionation of extracts from the cambial zone of *E. regnans*

* Expressed on the basis of fresh weight of material; all other results are on the basis of oven-dry material.
N.D., Not determined.

appreciable quantities of malic, citric and tartaric acids may be associated with the operation of the citric acid cycle either within the areas of secondary growth or within photosynthesizing cells; in the latter case excess production of these acids may result in their excretion from the photosynthesizing cells and their accumulation, after translocation, in the cambial zone.

Sucrose, D-glucose, D-fructose and *myo*-inositol, which were determined quantitatively by chromatography[4], represent more than 90 per cent of neutral fraction I; they were characterized by the formation of derivatives, by physical properties and by infra-red spectroscopy. *myo*-Inositol has not been isolated previously from cambial samples, and is of particular interest as a possible intermediate between carbohydrates and aromatic compounds and as a possible precursor of D-glucuronic acid[5].

The water extract of solid residue II contained material which could be precipitated on the addition of ethanol. The precipitate, during hydrolysis with dilute acids, yielded substances which were chromatographically identical with rhamnose, galactose, arabinose, xylose and galacturonic acid. The relatively large amounts of galactose and arabinose suggest that pectic substances may be present in the water-soluble polymer.

It has been suggested that substances with reactive groups are transported, generally in an inactivated state, to the regions of active secondary growth[6]. For example, glucose, fructose and galactose are usually translocated, in the assimilate stream, as sucrose and as higher oligosaccharides of the raffinose series of sugars[7]. Hence the water-soluble polymer may represent an inactivated mobile complex of monosaccharide residues which could be utilized, following enzymatic hydrolysis in the cambial regions, as base units which are immediately synthesized into cell-wall polysaccharides.

The water-soluble polymer appears to contain certain very reactive units because, during hydrolysis with dilute acids (even at room temperature), the insoluble material (solid residue III) is formed rapidly. Once formed it will not redissolve either in organic solvents or in aqueous solutions of acids or of alkalis. It does not seem to be related to lignin because it gives a negative Wiesner test[8], it is not aromatic (from infra-red spectroscopy) and it contains very few methoxyl groups. Infra-red spectroscopy indicated that the insoluble material is predominantly organic in nature and contains carbonyl and hydroxyl groups but does not contain carboxyl groups. The empirical formula $(C_{12}H_{17}O_{10})_x$ of the insoluble substance considered in conjunction with the foregoing evidence suggests that it may be formed by the acid-catalysed condensation of very reactive carbohydrate units.

We thank the Australian Micro-analytical Service for microanalyses, Mr. K. J. Harrington and Mr. H. G. Higgins for help in the preparation and interpretation of infra-red spectra, and Miss Ann Carle for help with the chromatography of polyphenolic substances.

Induction of Callus on Decapitated Hypocotyl of *Helianthus* by *Escherichia coli* and other Bacteria

In vitro cultures of angiosperm organs in association wit several common free-living bacteria have resulted in callu formation. The gross morphology and histology of thes calluses are similar to crown gall tumours produced the same time under similar conditions. Controls lackin the associated bacterium show little proliferation of cu surfaces.

Seeds of Giant Russian annual sunflower were surfac sterilized by removal of testa and immersion for 20 min 20 vol. hydrogen peroxide and germinated on 25 c.c. complete White's medium agar in tubes. When th etiolated seedlings had expanded the cotyledons, the hyp cotyls were severed below the cotyledonary node and th cut surface was inoculated with a loopful of a 48-h-o nutrient broth culture of the bacterium under test. F comparison, hypocotyls were also inoculated with *Agr bacterium tumefaciens* and controls consisted of cu hypocotyls either with a drop of nutrient broth or wit no treatment. The tubes were incubated at 25° C in th dark.

Within a week the hypocotyls with *Agrobacteriu* showed evident callus formation; both sets of controls ha either formed wound tissue with no further proliferation the terminal tissue had died. Over the same period rather low proportion (about 25 per cent) of the cut ends the hypocotyls inoculated with the bacteria under te began to proliferate and, by the time the nutrients in th agar were exhausted, had formed calluses comparab in size to those of the crown gall (Fig. 1). The bacter producing positive results were *E. coli*, *Pseudomon aeruginosa*, *Sarcina lutea* and *Aerobacter aerogenes*.

Since *E. coli* produced the most pronounced effects, was chosen for further study. Strains of this bacteriu re-isolated from the callus proved more virulent. The induced a high proportion (more than 75 per cent) positive results and the callus grew more rapidly.

Examples of the callus produced by *E. coli* and *Agr bacterium* were fixed and sectioned. In both there we similar proliferations of the vascular tissue. The prolife ation induced in the ground tissue by *E. coli* appear more regular but included irregular differentiation tracheary elements. Occasionally associated with th

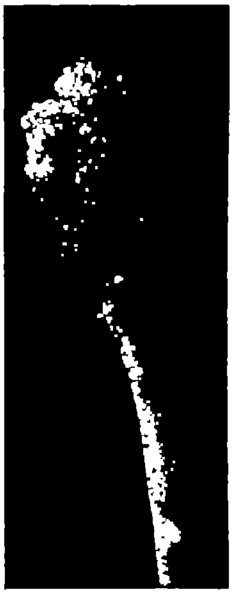

Fig. 1. Proliferation of decapitated hypocotyl of *Helianthus* inoculated with *Escherichia coli*

callusing induced by several bacteria was a distension of the hypocotyl, which might reach a maximum some distance below the cut surface. A full description of the morphogenetic responses will be published elsewhere.

In the early stages of these experiments, while the cut surfaces were still moist, the controls formed wound-healing tissue which simulated a small callus. This is consistent with the proliferation of wounded surfaces of many plants in humid atmospheres[1]. It seemed possible, therefore, that the bacterial cultures merely allowed callusing to continue by maintaining moisture at the cut surfaces. When the work was repeated with the surfaces of the controls kept moist, greater proliferation resulted, but nothing comparable with the bacteria-induced callus was produced.

Attempts to induce callus formation by inoculation of wounds on intact sunflower seedlings in glasshouse conditions were unsuccessful with *E. coli*, though 100 per cent successful with crown gall. This ineffectuality of *E. coli* we attribute to rapid wound healing in relatively dry air. Decapitated seedlings of sunflower grown on White's medium in the light, and intact seedlings grown on White's medium in the light in a humid atmosphere, have produced local stem swellings when a wound was inoculated with *E. coli*.

No reports of callus-induction by non-pathogenic bacteria are known to us and comments on these results would be appreciated. Zielinski[2] reports accelerated growth of carrot tissue cultures in association with an unnamed bacterium and Fallot[3] records increased rate of growth of tissue cultures of *Vitis rupestris* in association with *Bacillus megaterium*.

We thank Miss L. Williams, Department of Microbiology, University of Queensland, for confirming the identity of the cultures of *E. coli* used in our original inoculations and also those recovered from induced callus.

We also acknowledge the controlled environment facilities made available to one of us (D. E. G. S.) by the New Zealand Universities' Grants Committee.

Succession of Nematophagous Fungi during the Decomposition of Organic Matter in the Soil

ALTHOUGH nematophagous fungi have been intensively studied in agar cultures containing nematodes, and soil organic matter has commonly been used as a source of these fungi[1,2], little seems to be known of the succession of fungi in this biological group during the decomposition of organic matter in the soil. Preliminary work has accordingly been done to determine the nature of any succession with the view of further investigation.

A soil with a wide variety of species of indigenous nematophagous fungi was selected for examination. These comprised three retiary trap-formers, *Arthrobotrys oligospora*, *Dactylaria psychrophila*, and *Trichothecium cystosporium; Dactylella cionopaga*, a fungus producing modified adhesive hyphal branches as trapping organs; an unidentified zoopagaceous fungus with aseptate adhesive hyphae; an unidentified fungus with constricting-ring snares and three endozoic parasites *Acrostalagmus obovatus*, *Harposporium anguillulae* and *Nematoctonus leptosporus*. In pure culture and on nematode-infested agar the retiary trap-forming fungi grew vigorously and sporulated intensely. *Dactylella cionopaga* grew much more slowly and sporulation was relatively sparse. Neither of the unidentified fungi was isolated in pure culture but on agar containing nematodes both showed sparse and slow growth.

The soil was used fresh and unsterilized after being passed through a 7-mm mesh sieve and its moisture content was maintained as 50–55 per cent of the total water-holding capacity. Direct observation of the fungi in the soil was made using the agar disk technique[3]. A characteristic succession pattern was noted during the decomposition of both green manure, in the form of cabbage-leaf tissue, and carbohydrates as glucose or sucrose. The period during which the fungi were seen to be predaceously active continued for 7–11 weeks after the addition of amendments to the soil.

The nematophagous activity of the retiary trap-forming fungi increased, and, having reached a peak, declined during the first half of this period. The zoopagaceous fungus and *Dactylella cionopaga*, having played a subsidiary part as nematode-destroyers during this time, then increased in activity during the second half of the period and became the predominant components of the nematophagous complex. After reaching a peak of activity these in turn declined. The ring-forming organism was rarely observed and then only in the final stages of the succession. The endozoic parasites appeared sporadically during the whole of the succession, attacking a proportion of the nematodes available for infection.

Excluding the endozoic parasites the pattern of succession appears to bear no relation to the numbers of nematodes in the soil at any particular time and would seem rather to depend on growth rate and spore-production, organisms more vigorous in these respects appearing first followed by those less vigorous. However, the sequence may be related more fundamentally to the changes in the nutritional status of the soil microhabitats with time. Investigation of the nutritional requirements of the nematode-trapping fungi may help elucidate the problem.

Chemical and Immunological Comparisons of Allelic Immobilization Antigens in *Paramecium aurelia*

PURIFIED immobilization antigens of *Paramecium aurelia* (syngen 1) were obtained from stocks containing different alleles at the *D* locus[1] and compared by the technique of 'fingerprinting'[2,3]. Previously[4,5] the antigen has been shown to be a protein of molecular weight approximately 250,000. It was extracted by the salt–alcohol method of Preer[4] and purified by ammonium sulphate precipitation and chromatography on carboxymethyl cellulose. Tryptic digests were prepared from antigen denatured by reduction with 2-mercaptoethanol, alkylated with iodoacetic acid[6] and 'fingerprinted' by the method of Katz, Dreyer and Anfinsen[3], except that the chromatographic solvent was *n*-butanol/water/acetic acid (17 : 9 : 4) and the electrophoresis buffer had a *p*H of 4·2.

Nine naturally occurring allelic D types were examined and all were found to differ in the peptide patterns produced. The patterns were of the same general form, however, in contrast to two G serotypes (90G and 60G, controlled by alleles at another locus) which showed a radically different distribution of peptide spots. This

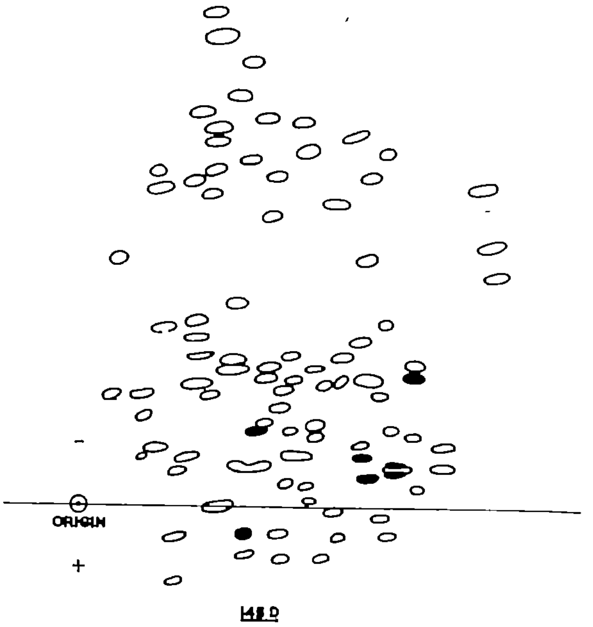

Fig. 1. Tracing of a fingerprint of antigen 145D. Chromatography horizontally and electrophoresis vertically, Shaded spots contain tryptophan

confirms the observations of Steers[7] with the A, B and D serotypes of syngen 4 of *P. aurelia*.

In our study of the D antigens, we found that genes at the *D* locus alone were concerned in specifying the structure of the isolated protein. This was shown by comparing two preparations of antigen 90D: one from stock 90 itself and the other from a strain containing the allele D^{90}, which, by repeated back-crossing, had been made nearly isogenic with the unrelated stock 60. The peptide patterns of the two were indistinguishable.

Since the patterns contain about 80 spots (Fig. 1), detailed analysis has so far been impracticable. However, comparisons were made between the nine D antigens by counting the numbers of differently situated spots, and these results are shown in Table 1. These numbers are assumed to be twice the number of altered peptides but represent only a minimum estimate of amino-acid replacements.

The immunological relationship between the various antigens was investigated by observing cross-reactions by the immobilization test. These results are shown in Table 2. The correlation between immunological diversity and number of peptide differences is quite evident. All members of the group of five D types which are indistinguishable from 60D show only small differences in peptide pattern while the types which are clearly distinguishable immunologically have many more peptide differences. The type 145D, which cross-reacts very strongly with 60D but can be differentiated, shows an intermediate number of differences.

As shown in Table 2 the antigens investigated were derived from material of exceedingly diverse geographical origin, and it is assumed that they can have only a very remote evolutionary connexion. It would thus be expected that mutations involving portions of the molecule not concerned with its antigenic specificity would be randomly distributed throughout the stocks. That so few peptide differences were found between types indistinguishable immunologically but of independent origin suggests that the antigenic site is a major portion of the molecule. Otherwise the number of peptide differences would be more nearly independent of the antigenic relationship.

Table 1. Pairwise Comparisons of 'Fingerprints' of Allelic Immobilization Antigens showing Numbers of Differently Situated Spots
(Blank spaces indicate no comparisons made)

	60D	33D	90D	103D
178D	2			
181D	4			
521D	3			
535D	6			
145D	10	20	20	20
33D	20	—	—	—
90D	20	10	—	—
103D	20	20	20	—

Table 2. Immunological Relations of Nine Different D-Type Immobilization Antigens in *P. aurelia*

Antigens	Origin of stocks	Antibodies Anti-60D (192)	Anti-41D (74)	Anti-103D (172)	Anti-33D (92)	Anti-90D (178)	(181
60D 178D 181D 521D 535D	Vermont Santiago, Chile Tokyo Paris Adelaide	*100*	*100*	< 5	< 5	< 5	< 5
145D	Paris	*100*	*100*	20	< 5	< 5	< 5
33D	Baltimore	80	10	< 5	*100*	25	< 5
90D	Pennsylvania	< 5	10	35	20	*100*	*100*
103D	Philadelphia	< 5	< 5	*100*	< 5	< 5	10

Cross-reactions are indicated as percentages of the homologous reactions (The numbers in parentheses under Anti-60D, etc., are serum numbers.)

It appears, therefore, that antigenic specificity is here due, not to a small number of chemical groups as is known for certain polysaccharide antigens, but to the cumulative effect of many amino-acids.

This work was supported by a grant from the Medical Research Council, and much helped by the Microbiological Research Establishment, Porton, with bulk preparation of material.

Hypergammaglobulinæmia in Mink Initiated by a Cell-free Filtrate

Aleutian disease in mink is a spontaneous, transmissible disease which can be used as a model for studying the pathogenetic mechanisms in certain immunological and connective tissue diseases[1]. Hypergammaglobulinæmia is a constant feature of the disease[1,2,3], and the severity of the natural and experimental disease appears to parallel the rise in γ-globulin[2,3]. The histological[5,6] and histochemical[7] changes resemble those of the connective tissue diseases of man. A genetic predisposition[4] as well as a familial occurrence[8] have been demonstrated.

We have shown that hypergammaglobulinæmia can be experimentally produced by the injection of tissue suspensions from naturally affected mink[2]. The active principle was found to be resistant to 0·3 per cent formalin at 5° C for 2 weeks but not for 40 weeks[2]. The work reported here was carried out to characterize further the active principle by filtration and ultra-centrifugation of affected tissue suspensions.

The mink used in these trials were from our own herd in which Aleutian disease has never naturally occurred. The number of mink in each treatment group as well as the genotypes are given in Table 1. The genotypes are designated as homozygous recessive (*aa*), heterozygous (*Aa*) or homozygous dominant (*AA*) for the Aleutian gene[4].

The tissues used for the preparation of the mocula were from *aa* mink with the natural disease. The spleens, livers, and kidneys were collected immediately after death and kept at − 26° C until used. Portions of these organs were ground in a Waring blender and diluted to 10^{-1} with phosphate buffered saline (*p*H 7·5). The suspension was then centrifuged for 1 h at 10,000 r.p.m. in a Servall odel RC-2 refrigerated centrifuge with an SS-34 rotor 0,500g) and the supernatant fluid removed. The pernatant fluid was then filtered through a Krueger 'E' d and the filtrate was centrifuged for 1 h at 35,000 p m. in a model L Spinco ultracentrifuge with a 40·3 gle head rotor (95,000g). The supernatant fluid was moved and the pellet resuspended in an equal volume phosphate buffered saline.

All mink except the non-injected controls received 2 ml. bcutaneously of inoculum. The original 10 per cent ude tissue suspension was injected into group I. Follow- g filtration and ultracentrifugation at 35,000 r.p.m., roup II received the supernatant fluid and group III ceived the resuspended pellet. Group IV served as non- jected controls.

Serum samples were collected prior to inoculation and gain when the trial was terminated 2 months following oculation. Filter-paper zone electrophoresis and total rum protein determinations were carried out as prev- usly described[1]. All the mink had normal serum protein alues before inoculation.

The post-injection serum protein values were com- ared with those of 19 experimentally affected animals and 9 non-affected animals originating from our herd[2]. The iteria for hypergammaglobulinæmia included: (1) γ- lobulin values of 2·0 g or more per 100 ml. of serum ontrol mean + 2 $S.D.$ = 1·99 g/100 ml.) with α- and β- lobulins within the normal range; (2) normal or elevated tal serum protein values; (3) normal or decreased bumin levels; and (4) albumin/globulin ratios of 1·0 or ss. Gross and histological studies on all mink will be e subject of another report.

ble 1. TOTAL NUMBER OF ANIMALS BY GENOTYPE IN EACH TREATMENT GROUP AND THE NUMBER DEVELOPING HYPERGAMMAGLOBULINÆMIA

roup	Treatment	Recipient genotypes Affected/No. injected *aa*	*Aa*	*AA*	Total No. Affected/total injected
I	Crude tissue suspension	5/5	1/3	2/2	8/10
II	Supernatant fluid following filtration and ultracentrifugation	1/5	0/4	1/6	2/15
III	Resuspended pellet following filtration and ultracentrifugation	5/5	3/4	2/6	10/15
IV	Non-injected controls	0/4	0/5	0/7	0/16

The results are summarized in Table 1 and indicate that n elevation of γ-globulin occurred in treatment groups I, I and III. All the homozygous recessive mink in groups I nd III showed a rise in γ-globulin, but only part of the eterozygous and homozygous mink responded in this anner. This difference in genotype susceptibility has een previously noted[3]. Two of 15 mink in group II had ypergammaglobulinæmia. One was an aa mink and the ther an AA. The mean serum protein values and the andard deviations of all groups are given in Table 2. tatistical analysis using analysis of variance[8] revealed a gnificant increase ($P < 0·01$) in γ-globulin and a signifi- ant decrease ($P < 0·01$) in albumin in groups I and III.

The filter excluded viable tissue cells and bacteria. If e cause of Aleutian disease were a soluble substance, ch as a soluble protein, it is probable that the active action would remain in the supernatant fluid. A part- ulate substance would be expected to settle during the cond centrifugation (95,000g for 1 h).

Changes in serum protein occurred in 66 per cent of the nimals given the sediment and in 80 per cent of the nimals given crude tissue suspension. The supernatant uid evoked a response in 13 per cent of the mink. The ncentration of the initiating factor, therefore, was higher in the sediment than in the supernatant fluid and the activity of the sediment was close to that of the crude tissue suspension. It would appear that the cause of hypergammaglobulinæmia in mink is a filterable substance which can be almost completely removed from aqueous suspension by ultracentrifugation at 95,000g for 1 h. It seems possible that this filterable substance could produce hypergammaglobulinæmia and other changes through one of several possible mechanisms: (1) stimulation of primitive mesenchymal cells to proliferate and form many plasma cells which produce hypergammaglobulinæmia; (2) initiation of an auto-immune response; or (3) initiation of an alteration which in turn is responsible for the pathological changes. At present, it is not known whether the elevated γ-globulin is antibody directed against a tissue or other antigen, but initial studies to characterize this γ-globulin indicate that it has an ultracentrifugation constant of approximately 7 S[5].

The finding of a filterable, cell-free substance which initiates changes in mink that resemble certain connective tissue diseases in man raises speculation as to possible similar mechanisms involved in these human diseases.

This investigation was supported in part by U.S. Public Health Service grant $A5400$, training grant $2G$–414 and the Mink Farmers' Research Foundation.

Note. While this work was in progress, Dr. J. D. Russell, Madison, Wisconsin, was able to cause hypergammaglobulinæmia in mink using Berkefeld N filtrates.
